

MODULI AND TILTING I. QUIVERS

JIARUI FEI

ABSTRACT. We use tilting theory and birational geometry to study moduli spaces of quiver representations. From certain “representable” functor, we construct a birational transformation from the moduli space of representations of one quiver to another new quiver with one vertex less. The dimension vector and the stability for the new moduli are determined functorially. We introduce several relative notions of stability to study such a birational transformation. The essential case is proven to be the usual blow-ups. Moreover, we compare the induced ample divisors for the two moduli. We illustrate this theory by various examples.

1. INTRODUCTION

We propose to use tilting theory and birational geometry to study moduli spaces of algebras in the sense of geometric invariant theory, e.g. King [13]. The idea is very simple and can be roughly described as follows. For any algebra A , we denote by $\text{Mod}(A)$ the abelian category of finite-dimensional left modules of A and $\text{Rep}_\alpha(A)$ the usual affine variety of α -dimensional representations of A . To study the moduli space of representations in an irreducible component $\mathcal{C}$ of $\text{Rep}_\alpha(A)$, we appropriately choose a functor $F : \text{Mod}(A) \rightarrow \text{Mod}(B)$ such that F maps a general orbit in an irreducible component $\mathcal{C}$ to a general orbit in an irreducible component $\mathcal{C}_F$. Then F induces a rational map f from the moduli stacks $\text{Mod}_{\mathcal{C}}(A)$ to $\text{Mod}_{\mathcal{C}_F}(B)$. Let $\text{Mod}_{\mathcal{C}}^\sigma(A)$ be the GIT quotient of σ -semi-stable representations of $\mathcal{C}$. It is a quotient of an open substack of $\text{Mod}_{\mathcal{C}}(A)$, then f descends to a rational map of the GIT quotients $\text{Mod}_{\mathcal{C}}^\sigma(A)$ and $\text{Mod}_{\mathcal{C}_F}^{\sigma_F}(B)$ for certain stability σ_F . If we can understand this rational map and the quotient downstairs, then the other one can be understood as well.

Although this idea can be applied to any algebra, as a first attempt we only focus on finite-dimensional quiver algebras. We have the following reasons for this. The varieties of representations are all affine spaces, in particular smooth and irreducible. Otherwise, one has to detect irreducible components and works with possibly highly singular varieties. For smooth variety, Mumford’s semi-invariant construction gives all possible good quotients in the category of varieties or schemes. Moreover, the simple nature of quiver algebras allow us to refine most of general results. In fact, we think that it is even possible to do some classification in low dimensions. Finally, this theory has a good application in Schubert calculus [7, Section 7]. Since we hope to stay in the world of quivers, the functors that we pick are very special. They are so-called orthogonal projections, introduced by Geigle

and Lenzing [9]. Its induced rational map turns out to be birational. This approach may be also suggested by Schofield in the end of the introduction of [18]. In [18], Schofield studied the birational equivalence among the moduli spaces targeting the rationality problem. However, we focus more on the geometry of the birational transformation. We also show by example that the answer to the question proposed in [18, Introduction] is negative in general.

Here we first provide some preliminary background on the moduli spaces of quiver representations. For a good introduction or more detailed treatment, we recommend [13, 15]. Let Q be a finite quiver with the set of vertices Q_0 and the set of arrows Q_1 . If $a \in Q_1$ is an arrow, then ta and ha denote its tail and its head respectively. Throughout k is a algebraically closed field of characteristic 0. Fix a *dimension vector* α , the space of all α -dimensional representations is

$$\text{Rep}_\alpha(Q) := \bigoplus_{a \in Q_1} \text{Hom}(k^{\alpha(ta)}, k^{\alpha(ha)}).$$

The group $\text{GL}_\alpha := \prod_{v \in Q_0} \text{GL}_{\alpha(v)}$ acts on $\text{Rep}_\alpha(Q)$ by the natural base change. This action has a *kernel*, which is the multi-diagonally embedded k^* . Two representations $M, N \in \text{Rep}_\alpha(Q)$ are isomorphic if they lie in the same GL_α -orbit. Any *character* or *weight* of GL_α has the form

$$\{g(v) \mid v \in Q_0\} \rightarrow \prod (\det g(v))^{\sigma(v)}, \quad \sigma(v) \in \mathbb{Z}.$$

We define the subgroup GL_α^σ to be the kernel of the character map. The semi-invariant ring $\text{SIR}_\alpha^\sigma(Q) := k[\text{Rep}_\alpha(Q)]^{\text{GL}_\alpha^\sigma}$ of weight σ is σ -graded: $\bigoplus_{n \geq 0} \text{SI}_\alpha^{n\sigma}(Q)$, where

$$\text{SI}_\alpha^\sigma(Q) := \{f \in k[\text{Rep}_\alpha(Q)] \mid g(f) = \sigma(g)f, \forall g \in \text{GL}_\alpha\}.$$

A representation $M \in \text{Rep}_\alpha(Q)$ is called σ -*semi-stable* if there is some non-constant $f \in \text{SIR}_\alpha^\sigma(Q)$ such that $f(M) \neq 0$. It is called *stable* if the orbit $\text{GL}_\alpha^\sigma M$ is closed of dimension $\dim \text{GL}_\alpha^\sigma - 1$. We denote the set of all σ -semi-stable (resp. σ -stable, σ -unstable) representations in $\text{Rep}_\alpha(Q)$ by $\text{Rep}_\alpha^{\sigma\text{-ss}}(Q)$ (resp. $\text{Rep}_\alpha^{\sigma\text{-st}}(Q)$, $\text{Rep}_\alpha^{\sigma\text{-un}}(Q)$). When $\text{Rep}_\alpha^{\sigma\text{-ss}}(Q)$ (resp. $\text{Rep}_\alpha^{\sigma\text{-st}}(Q)$) is non-empty, we say that α is σ -semi-stable (resp. σ -stable). Based on Hilbert-Mumford criterion, King provides a simple criterion for the stability of a representation.

Lemma 1.1. [13, Proposition 3.1] *A representation M is σ -semi-stable (resp. σ -stable) if and only if $\sigma(\dim_Q(L)) \leq 0$ (resp. < 0) for any non-trivial subrepresentation L of M .*

The GIT quotient with respect to a linearization of character σ is

$$\text{Mod}_\alpha^\sigma(Q) := \text{Proj}(\bigoplus_{n \geq 0} \text{SI}_\alpha^{n\sigma}(Q)),$$

which is projective over the ordinary quotient $\text{Spec}(k[\text{Rep}_\alpha(Q)]^{\text{GL}_\alpha})$. If we assume that Q has no oriented cycles, then $k[\text{Rep}_\alpha(Q)]^{\text{GL}_\alpha} = k$, so the GIT quotient is projective. In this notes, we assume that Q has no oriented cycles, or equivalently the associated path algebra kQ is finite-dimensional. So the category $\text{Rep}(Q)$ has enough projective and injective objects.

The induced quotient map $q : \text{Rep}_\alpha^{\sigma\text{-ss}}(Q) \rightarrow \text{Mod}_\alpha^\sigma(Q)$ is a *good categorical quotient* and the restriction of q on $\text{Rep}_\alpha^{\sigma\text{-st}}(Q)$ is a *geometric quotient*. In general, the quotient $\text{Mod}_\alpha^\sigma(Q)$ may be singular, but they are always normal and have *rational singularities* because in general these two properties are inherited by the invariant ring.

Before treating the general case, we would like to mention several reduction steps. If α is strictly σ -semi-stable, then it has a σ -stable decomposition: $\alpha = c_1\alpha_1 + c_2\alpha_2 + \cdots + c_r\alpha_r$ [7, 3.2]. [7, Theorem 3.20] says that in this case the GIT quotient $\text{Mod}_\alpha^\sigma(Q)$ is just a symmetric product of $\text{Mod}_{\alpha_i}^\sigma(Q)$ s. So we only need to deal with the more geometric cases when α is σ -stable. Next, if the quotient is 1-dimensional, it is a rational normal curve, which must be $\mathbb{P}^1$. So we will focus on the case when the quotient has dimension at least 2. The dimension of the quotient is given by

$$\dim \text{Rep}_\alpha(Q) - (\dim \text{GL}_\alpha^\sigma - 1) - 1 = 1 - \langle \alpha, \alpha \rangle_Q,$$

where $\langle \cdot, \cdot \rangle_Q$ is the *Euler form* associated to Q . So in this case, α must be a *non-isotropic imaginary Schur root*. Here, non-isotropic imaginary means that $\langle \alpha, \alpha \rangle_Q < 0$ and Schur root means that $\text{Hom}_Q(M, M) = k$ for general $M \in \text{Rep}_\alpha(Q)$.

Let $\Sigma_\alpha(Q)$ denote the *G-ample cone* of the action, that is, the set of all weights σ such that α is σ -semi-stable. It turns out that such a weight σ must be of the form $\sigma_\beta := -\langle \cdot, \beta \rangle_Q$.

For any $N \in \text{Rep}_\beta(Q)$, we apply the functor $\text{Hom}_Q(-, N)$ to the *canonical resolution* of M :

$$(1.1) \quad 0 \rightarrow \bigoplus_{a \in Q_1} P_{ha} \otimes M(ta) \rightarrow \bigoplus_{v \in Q_0} P_v \otimes M(v) \rightarrow M \rightarrow 0,$$

then we get the following exact sequence

$$(1.2) \quad \text{Hom}_Q(M, N) \hookrightarrow \bigoplus_{v \in Q_0} \text{Hom}(M(v), N(v)) \xrightarrow{\phi_N^M} \bigoplus_{a \in Q_1} \text{Hom}(M(ha), N(ta)) \twoheadrightarrow \text{Ext}_Q(M, N).$$

If $\langle \alpha, \beta \rangle_Q = 0$, then ϕ_N^M is a square matrix. Following Schofield [16], we define $c(M, N) := \det \phi_N^M$. Note that $c(M, N) \neq 0$ if and only if $\text{Hom}_Q(M, N) = \text{Ext}_Q(M, N) = 0$. We denote $c_N := c(-, N)$ and dually $c^M := c(M, -)$. Note that $c_N \in \text{SI}_\alpha^{\sigma_\beta}(Q)$. We call them Schofield's semi-invariants. In fact, they span $\text{SI}_\alpha^{\sigma_\beta}(Q)$ over k [6, Theorem 1]. So if M is a σ_β -semi-stable representation, then there is some $N \in \text{Rep}_{n\beta}(Q)$ for some $n \in \mathbb{N}$ such that $c_N(M) = c(M, N) \neq 0$. Clearly c_N defines a GL_α -invariant divisor on $\text{Rep}_\alpha(Q)$ and we denote it by C_N . Let $q : \text{Rep}_\alpha^{\sigma_\beta, \text{ss}}(Q) \rightarrow \text{Mod}_\alpha^{\sigma_\beta}(Q)$ be the quotient map, then C_N induces an ample effective divisor $q_*(C_N)$ on $\text{Mod}_\alpha^{\sigma_\beta}(Q)$. All divisors of this form are linear equivalent and we denote it by D_β . So we get not only a projective quotient but also an induced ample divisor for free. Its space of global section $H^0(\text{Mod}_\alpha^{\sigma_\beta}(Q), D_\beta)$ is isomorphic to $\text{SI}_\alpha^{\sigma_\beta}(Q)$. Certainly, there are dual statements for c^M .

For any dimension vector α , there is a canonical choice of weight, which is

$$\sigma_{ac} = \langle \alpha, \cdot \rangle_Q - \langle \cdot, \alpha \rangle_Q = \langle \alpha + \tau^{-1}\alpha, \cdot \rangle_Q = -\langle \cdot, \alpha + \tau\alpha \rangle_Q.$$

To simplify our notation, sometimes we denote the dimension vector $\alpha + \tau\alpha$ also by ac . One importance of this weight was discovered by Schofield in [17, Theorem 6.1].

Proposition 1.2. *α is a Schur root if and only if it is σ_{ac} -stable.*

This notes is organized as follows. In Section 2, we review some basics of the orthogonal projection from [9, 16]. A concrete description of the representability of this functor (Lemma 2.5) may be new. Next, we make a crucial definition of E -regular representations and exhibit a morphism at the level of moduli stacks.

After specializing to the orthogonal case, we provide a family of surface examples. In Section 3, we introduce the fundamental rank to prove some basic properties of the exceptional set $\mathcal{E}_\alpha$ including its irreducibility. In Section 4, we prove several simple results on homological algebra for later use. In Proposition 4.3, we give an easy way to estimate the dimension of fibers of an orthogonal projection. In Section 5, we introduce a series of relative notions to study how the stability changes under the orthogonal projections. After that, we give our first main result Theorem 5.10 on a functorial construction of birational transformations of the GIT quotients. We illustrate this result by continuing the examples in Section 2. One important corollary builds up the connection between the functorial construction and the wall-crossing, which leads to the important definition of the core of the G -ample cone. The functorial construction is further refined in Section 6 by using a result of Thaddeus. We show in Theorem 6.3 that the essential case of that birational transformation is the usual blow-up. This is our second main result. It is furnished with an interesting example in dimension three. In Section 7, we compare the induced ample divisors under the birational transformation. This is our third main result Theorem 7.6. We also illustrate it by examples discussed before. We consider in particular the induced divisors from the anti-canonical characters and show it agree with the anti-canonical class in most cases.

Finally, we want to make three little remarks on our language and notations. Although the moduli spaces we interested in are the classical GIT quotients, for our convenience we introduce the moduli stacks because the functors that we consider work well only at the level of moduli stacks. We do not need any advanced theory on algebraic stacks. Naively one can think of the moduli stacks in this notes as certain geometric objects parameterizing equivalent representations. We use Rep to denote the affine variety of representations and replace Rep by Mod to denote the corresponding moduli stack. For example, $\text{Mod}_\alpha(Q)$ is the moduli stack of all α -dimensional representations of Q , and similarly $\text{Mod}_\alpha^{\sigma_\beta \cdot \text{ss}}(Q)$ is the moduli stack of all α -dimensional σ_β -semi-stable representations. Note the difference between the moduli stack $\text{Mod}_\alpha^{\sigma_\beta \cdot \text{ss}}(Q)$ and the GIT quotient $\text{Mod}_\alpha^{\sigma_\beta}(Q)$. When used without any subscript or superscript, it coincides with the module category. We indulge ourself in this abuse of notation.

The second remark is that if we put an irreducible variety in an argument for a single representation, we mean a general representation in that variety. For example, $\text{hom}_Q(M, C^M)$ means the dimension of $\text{Hom}_Q(M, N)$, where N is a general representation of C^M . If the variety is $\text{Rep}_\alpha(Q)$, we abbreviate it by α , e.g. $\text{hom}_Q(\alpha, C^M)$. If the variety is a subvariety of a product of two varieties, then this variety can replace a bi-argument. For example, $\text{hom}_Q(C)$ means the dimension of $\text{Hom}_Q(M, N)$ for a general element $(M, N) \in C$.

Finally, our vectors are exclusively row vectors. If an arrow of a quiver is denoted by a lowercase letter, then we write the corresponding capital letter for its linear map of a representation. For any other unexplained terminology or notation in the representation theory of quivers, we refer the readers to [7].

2. ORTHOGONAL PROJECTION

Let us review some basic facts about the orthogonal projections, first at the level of unimodular bilinear form and later at the level of module category. Let V be a unimodular lattice with bilinear form $\langle \cdot, \cdot \rangle$ and ϵ be a root of V , i.e., $\langle \epsilon, \epsilon \rangle = 1$. The

right (resp. left) orthogonal lattice $\epsilon^\perp$ (resp. ${}^\perp\epsilon$) is the sublattice

$$\{\alpha \in V \mid \langle \epsilon, \alpha \rangle = 0\} \text{ (resp. } \{\alpha \in V \mid \langle \alpha, \epsilon \rangle = 0\}).$$

The Coxeter transformation τ is the unique linear transformation determined by $\langle \alpha, \beta \rangle = -\langle \beta, \tau\alpha \rangle$. Clearly $\epsilon^\perp = {}^\perp\tau\epsilon$, so we can focus on the right one. Following [14], we define the orthogonal projection $\pi_\epsilon : V \rightarrow \epsilon^\perp$ and the dual projection $\pi_\epsilon^\vee : V \rightarrow \epsilon^\perp$ by

$$\pi_\epsilon(\alpha) = \alpha - \langle \epsilon, \alpha \rangle \epsilon \text{ and } \pi_\epsilon^\vee(\alpha) = \alpha + \langle \epsilon, \alpha \rangle \tau\epsilon.$$

Clearly for $\alpha \in V$ and $\beta \in \epsilon^\perp$, we have that

$$\langle \alpha, \beta \rangle = \langle \pi_\epsilon \alpha, \beta \rangle \text{ and } \langle \beta, \alpha \rangle = \langle \beta, \pi_\epsilon^\vee \alpha \rangle.$$

A direct calculation can verify that $\langle \alpha, \beta \rangle = -\langle \beta, \pi_\epsilon^\vee \tau \alpha \rangle = -\langle \pi_\epsilon \tau^{-1} \beta, \alpha \rangle$ for $\alpha, \beta \in \epsilon^\perp$. In particular, $\pi_\epsilon^\vee \tau$ is the Coxeter transformation for $\epsilon^\perp$ and its inverse is $\pi_\epsilon \tau^{-1}$ [14, Corollary 18.1].

Let Q be a finite quiver without oriented cycles. For two kQ -module M and N , M is said to be left *orthogonal* to N denoted by $M \perp N$ if $\text{Hom}_Q(M, N) = \text{Ext}_Q(M, N) = 0$. In this case we also say that N is right orthogonal to M . The right *orthogonal category* $M^\perp$ is the abelian subcategory $\{N \in \text{Mod}(Q) \mid M \perp N\}$. A kQ -module E is called *exceptional* if $\text{Hom}_Q(E, E) = k$ and $\text{Ext}_Q(E, E) = 0$, so the dimension vector of E corresponds to a *real* Schur root ϵ . We specialize some general results in [9] (see also [16]) to the quiver case.

Lemma 2.1. [9, Proposition 3.2, 3.5] *$E^\perp$ is a reflective subcategory of $\text{Mod}(Q)$, i.e., there is a functor $\tilde{\pi}_E : \text{Mod}(Q) \rightarrow E^\perp$ left adjoint to the inclusion functor $E^\perp \rightarrow \text{Mod}(Q)$. In particular, $\tilde{\pi}_E$ is right exact and compatible with projective presentations.*

Sketch of proof. It is useful to recall the construction in [9], which is depicted by the following diagram. The row is the *universal extension* and the column is the *universal homomorphism*.

$$\begin{array}{ccccc} & & E^h & & \\ & & \downarrow & & \\ M \hookrightarrow & M' & \twoheadrightarrow & E^e & \\ & \searrow \scriptstyle r_M & \downarrow & & \\ & & \tilde{\pi}_E(M) & & \end{array}$$

Here, the universal extension means the extension universal with respect to the property that the connecting morphism $\text{Hom}_Q(E, E^e) \xrightarrow{\delta} \text{Ext}_Q(E, M)$ in the long exact sequence is an isomorphism. Similarly, we mean by the universal homomorphism.

Alternatively, we can change the order of taking the universal extension and the universal homomorphism, but this leads to the same construction.

$$\begin{array}{ccccc}
 E^h & \longrightarrow & M & \longrightarrow & M'' \\
 & & \searrow r_M & & \downarrow \\
 & & & & \tilde{\pi}_E(M) \\
 & & & & \downarrow \\
 & & & & E^e
 \end{array}$$

Note that the composition r_M is the universal homomorphism from M to an object of $E^\perp$. $\square$

Definition 2.2. The *basic set* $b(M)$ of a module M consists of all the non-isomorphic direct summands of M . We call M *basic* if its direct summands are all pairwise non-isomorphic.

A kQ -module T is called *partial tilting* if $\text{Ext}_Q(T, T) = 0$. A partial tilting module is called *tilting* if its direct summands generate the category $\text{Mod}(Q)$. This is equivalent to say that the cardinality of the basic set of T is equal to the number of vertices $|Q_0|$ [2, Proposition VI.4.4].

Remark 2.3. If P_v is the indecomposable projective module corresponding to a vertex v , then applying $\tilde{\pi}_E$ to P_v is particularly simple. If E is not projective, then $\text{Hom}_Q(E, P_v) = 0$; otherwise $\text{Ext}_Q(E, P_v) = 0$. Clearly, $\tilde{\pi}_E(kQ) = \bigoplus_{v \in Q_0} \tilde{\pi}_E(P_v)$ is partial tilting. Applying $\text{Hom}_Q(-, E)$ to the construction of Lemma 2.1, we see that $\text{Ext}_Q(\tilde{\pi}_E(kQ), E) = 0$, so $\tilde{\pi}_E(kQ) \oplus E$ is a tilting module for $\text{Mod}(Q)$. Let P_b be a direct sum of elements in $b(\tilde{\pi}_E(kQ))$, then the quiver of $\text{End}_Q(P_b)$ has $|Q_0| - 1$ vertices and no oriented cycles.

Corollary 2.4. [16, Theorem 2.3] *The orthogonal category $E^\perp$ is (Morita) equivalent to representations of a quiver Q_E having no oriented cycles with $|Q_0| - 1$ vertices. The inverse functor $\iota_E : \text{Mod}(Q_E) \rightarrow E^\perp$ is a full exact embedding into $\text{Mod}(Q)$.*

We called the functor $\tilde{\pi}_E$ in Lemma 2.1 the (right) *orthogonal projection through* E and its composition with the equivalence in Lemma 2.4 the (right) *orthogonal projection to* Q_E , denoted by $\pi_E : \text{Mod}(Q) \rightarrow \text{Mod}(Q_E)$. Sometimes we do not distinguish $E^\perp$ and $\text{Mod}(Q_E)$ if no confusion is possible.

If E is not projective, then everything above has a dual statement for the left orthogonal category ${}^\perp E$ and left orthogonal projection ${}_E \tilde{\pi}$ and ${}_E \pi$. Let τ be the classical AR-transformation [2, IV.2] on $\text{Mod}(Q)$. By the AR-duality [2, Theorem IV.2.13], $E^\perp = {}^\perp \tau E$. We define the dual right orthogonal projection $\pi_E^\vee := {}_\tau E \tilde{\pi}$, the left orthogonal projection through τE . Let $I = \bigoplus_{v \in Q_0} I_v = kQ^{\text{op}}$, then the dual of Lemma 2.1 implies that $b(\tilde{\pi}_E^\vee(I))$ contains all the indecomposable injective module in $E^\perp$. We denote I_b the direct sum of all elements in $b(\tilde{\pi}_E^\vee(I))$.

It is well-known [20] that an adjoint pair between module categories must be representable by a bimodule. The next lemma says that the bimodule for $\tilde{\pi}_E$ is explicitly given by $b(\tilde{\pi}_E^\vee(I))$.

Lemma 2.5. $\tilde{\pi}_E(M) = \text{Hom}_Q(-, \tilde{\pi}_E^\vee(I))^*$, so $\pi_E(M) = \text{Hom}_{Q_E}(-, I_b)^*$.

Proof. First, we treat the case when $M = P$ is projective. Apply the functor $\mathrm{Hom}_Q(-, \tilde{\pi}_E^\vee(I))^*$ to the exact sequence $0 \rightarrow P \rightarrow \tilde{\pi}_E(P) \rightarrow E^e \rightarrow 0$, then we get $\mathrm{Hom}_Q(E^e, \tilde{\pi}_E^\vee(I))^* \leftarrow \mathrm{Hom}_Q(\tilde{\pi}_E(P), \tilde{\pi}_E^\vee(I))^* \leftarrow \mathrm{Hom}_Q(P, \tilde{\pi}_E^\vee(I))^* \leftarrow \mathrm{Ext}_Q(E^e, \tilde{\pi}_E^\vee(I))^*$. Since the first and last term vanish and $\tilde{\pi}_E^\vee$ is right adjoint to the inclusion functor,

$$\mathrm{Hom}_Q(\tilde{\pi}_E(P), \tilde{\pi}_E^\vee(I))^* = \mathrm{Hom}_Q(\tilde{\pi}_E(P), I)^* = \tilde{\pi}_E(P).$$

Hence $\mathrm{Hom}_Q(P, \tilde{\pi}_E^\vee(I))^* \cong \tilde{\pi}_E(P)$.

Now for any representation M , we apply $\mathrm{Hom}_Q(-, \tilde{\pi}_E^\vee(I))^*$ to its projective resolution $0 \rightarrow P_1 \rightarrow P_0 \rightarrow M \rightarrow 0$. Comparing

$$\mathrm{Hom}_Q(P_1, \tilde{\pi}_E^\vee(I))^* \rightarrow \mathrm{Hom}_Q(P_0, \tilde{\pi}_E^\vee(I))^* \rightarrow \mathrm{Hom}_Q(M, \tilde{\pi}_E^\vee(I))^* \rightarrow 0$$

with $\tilde{\pi}_E(P_1) \rightarrow \tilde{\pi}_E(P_0) \rightarrow \tilde{\pi}_E(M) \rightarrow 0$, We find that $\mathrm{Hom}_Q(M, \tilde{\pi}_E^\vee(I))^* \cong \tilde{\pi}_E(M)$ by the natural functoriality. $\square$

The equivalence in Corollary 2.4 induces a linear isometry between the K_0 -groups equipped with the Euler forms. In particular, $\dim_Q(M) = \dim_Q(N) \iff \dim_{Q_E}(\pi_E(M)) = \dim_{Q_E}(\pi_E(N))$. In general, we consider any dimension vector α . Under the functor π_E , general elements in $\mathrm{Rep}_\alpha(Q)$ maps to $\mathrm{Mod}_{\alpha_E}(Q_E)$ for some dimension vector α_E . We also have the dual notion $\alpha_E^\vee$ for the functor $\pi_E^\vee$.

Let ϵ be a real root of Q . We denote by $\tilde{\pi}_\epsilon$ the right orthogonal projection on the K_0 -group of $\mathrm{Mod}(Q)$ equipped with the Euler form $\langle \cdot, \cdot \rangle_Q$, i.e., $\tilde{\pi}_\epsilon(\alpha) = \alpha - \langle \epsilon, \alpha \rangle_Q \epsilon$. Similarly, we write π_ϵ for the composition of $\tilde{\pi}_\epsilon$ with the linear isometry induced by the equivalence in Lemma 2.4 and ι_ϵ for the inverse of this linear isometry. To simplify our notation, sometimes we write $\tilde{\alpha}_\epsilon := \tilde{\pi}_\epsilon(\alpha)$, $\alpha_\epsilon := \pi_\epsilon(\alpha)$, and $\alpha^\epsilon := \iota_\epsilon(\alpha)$. We need the obvious dual notions $\tilde{\pi}_\epsilon^\vee$, $\pi_\epsilon^\vee$, and $\tilde{\alpha}_\epsilon^\vee$, $\alpha_\epsilon^\vee$ later.

Definition 2.6. A representation $M \in \mathrm{Rep}_\alpha(Q)$ is called *E-regular* if $\dim_Q(\tilde{\pi}_E(M)) = \tilde{\alpha}_\epsilon$ or equivalently $\dim_{Q_E}(\pi_E(M)) = \alpha_\epsilon$. We denote the set of all *E-regular* representations by E^{reg} and $E^{\mathrm{reg}} \cap \mathrm{Rep}_\alpha(Q)$ by $\mathrm{Rep}_\alpha(E^{\mathrm{reg}})$.

Remark 2.7. It is clear from the construction of Lemma 2.1 that M is *E-regular* if and only if the universal homomorphism $E^h \rightarrow M$ is injective. Since α is the least possible dimension for $\tilde{\pi}_E(M)$ and the function $\dim \mathrm{Hom}$ is upper semi-continuous, we see from Lemma 2.5 that $\mathrm{Rep}_\alpha(E^{\mathrm{reg}})$ is open in $\mathrm{Rep}_\alpha(Q)$.

Lemma 2.8. *The functor π_E induces a morphism $\mathrm{Rep}_\alpha(E^{\mathrm{reg}}) \rightarrow \mathrm{Mod}_{\alpha_\epsilon}(Q_E)$.*

This follows immediately from the definition of *E-regularity* and the representability of the functor π_E . However, in general there is no algebraic morphism from $\mathrm{Rep}_\alpha(E^{\mathrm{reg}})$ to the affine variety $\mathrm{Rep}_{\alpha_\epsilon}(Q_E)$ as we will see in the examples below.

Let us specialize the above discussion to the orthogonal case.

Definition 2.9. We say that E is left orthogonal to a dimension vector α , denoted by $E \perp \alpha$, if $\mathrm{Rep}_\alpha(E^\perp) := E^\perp \cap \mathrm{Rep}_\alpha(Q)$ is non-empty. We say E is left exceptional to α if in addition $\mathcal{E}_\alpha := \mathrm{Rep}_\alpha(E^{\mathrm{reg}}) \setminus E^\perp$ is non-empty. We call $\mathcal{E}_\alpha$ an *exceptional set* in $\mathrm{Rep}_\alpha(Q)$ with respect to E . It has codimension one in $\mathrm{Rep}_\alpha(Q)$ by Remark 2.7.

The following lemma is a nice application of Luna's étale slice.

Lemma 2.10. [16, Theorem 3.2] *If $E \perp \alpha$, then $\mathrm{Rep}_\alpha(E^\perp)$ is isomorphic to the homogeneous fiber space $\mathrm{GL}_\alpha \times_{\mathrm{GL}_{\alpha_\epsilon}} \mathrm{Rep}_{\alpha_\epsilon}(Q_E)$.*

Since any representation in $E^\perp$ is trivially E -regular, we get an epimorphism $E^{\text{reg}} = \text{Rep}_\alpha(E^\perp) \amalg \mathcal{E}_\alpha \rightarrow \text{Mod}_{\alpha_\epsilon}(Q_E)$ by Lemma 2.8 and 2.10.

Example 2.11. Consider the quiver B^1

with dimension vector $\alpha = (1, 1, 1)$. Then the only exceptional representation E left orthogonal to α is $0 \rightarrow P_2 \rightarrow P_1 \rightarrow E \rightarrow 0$. So $M \notin E^\perp$ if the map D_1 is zero. Then $\text{hom}_Q(E, M) = 1$ and E is a subrepresentation of M , and thus $M \in \mathcal{E}_\alpha$. So $\text{Rep}_\alpha(E^{\text{reg}})$ is the whole $\text{Rep}_\alpha(B^1)$ and $\tilde{\pi}_E$ crashes $\mathcal{E}_\alpha$ to a single module $\tilde{N}_1$ represented by $\{A_1 = B_1 = 0, C_1 = D_1 = 1\}$.

Let us compute B_E^1 and α_ϵ . We observe that $\tilde{\pi}_E(P_1) = P_1, \tilde{\pi}_E(P_2) = P_1$, and $\tilde{\pi}_E(P_3) = P_3$. So B_E^1 is the three-arrow Kronecker Quiver Θ_3 with $\alpha_\epsilon = (1, 1)$. Let us denote the three arrows by a, b, c , then the morphism $\text{Rep}_\alpha(E^\perp) \rightarrow \text{Rep}_{\alpha_\epsilon}(\Theta_3)$ can be explicitly described as $A = A_1 D_1, B = B_1 D_1$, and $C = C_1$. So $\pi_E(\mathcal{E}_\alpha)$ is represented by $\{A = B = 0, C = 1\}$.

Consider the quiver B^2

with dimension vector $\alpha = (1, 1, 1, 1)$. Then there are three exceptional representations left orthogonal to α . They are

$$0 \rightarrow P_3 \rightarrow P_v \rightarrow E_v \rightarrow 0, v = 1, 2$$

$$0 \rightarrow P_4 \rightarrow P_3 \rightarrow E_3 \rightarrow 0$$

The same discussion as above gives us $(E_i)_\alpha^{\text{reg}} = \text{Rep}_\alpha(B^2)$ for $i = 1, 2, 3$. Let $E = E_2$. To compute B_E^2 , we observe that $\tilde{\pi}_E(P_1) = P_3 \rightarrow P_2 \oplus P_1, \tilde{\pi}_E(P_2) = P_2, \tilde{\pi}_E(P_3) = P_2$, and $\tilde{\pi}_E(P_4) = P_4$. So $B_E^2 = B^1$ with $\alpha_\epsilon = (1, 1, 1)$. The morphism $\text{Rep}_\alpha(E^\perp) \rightarrow \text{Rep}_{\alpha_\epsilon}(B^1)$ can be explicitly described as

$$\begin{cases} A_1 = C_2^{-1} A_2, \\ B_1 = B_2, \\ C_1 = E_2 C_2, \\ D_1 = D_2. \end{cases}$$

Note that this morphism cannot be extended to whole $\text{Rep}_\alpha(B^2)$.

By symmetry $B_{E_1}^2 = B^1$ and $\alpha_{\epsilon_1} = (1, 1, 1)$. However, $B_{E_3}^2$ is the quiver $\Theta_{2,2}$:

$$1 \xrightarrow[a]{b} 2 \xrightarrow[d]{c} 3.$$

with $\alpha_{\epsilon_3} = (1, 1, 1)$. We claim that there is no exceptional representation orthogonal to $(1, 1, 1)$ for $\Theta_{2,2}$. If there is one with dimension $\epsilon = (x, y, z)$, then $\langle \epsilon, \alpha_{\epsilon_3} \rangle_Q = 0$ and $\langle \epsilon, \epsilon \rangle_Q = 1$. Elementary calculation can show that $2(x^2 - xy) = 1$, which

is impossible. So the answer to the question in [18, introduction] is negative in general.

Consider the quiver B^3

with dimension vector $\alpha = (1, 1, 1, 1, 1)$. Then there are six exceptional representations left orthogonal to α . They are

$$0 \rightarrow P_v \rightarrow P_u \rightarrow E_{uv} \rightarrow 0,$$

where $u = 1, 2, 3, v = 4, 5$. It is easy to check that $(E_{uv})_\alpha^{\text{reg}} = \text{Rep}_\alpha(B^3)$. Let $E = E_{35}$. To compute B_E^3 , we observe that $P_3, P_4 \in E^\perp$, $\tilde{\pi}_E(P_5) = P_3$, and $\tilde{\pi}_E(P_v) = P_5 \rightarrow P_3 \oplus P_v$ for $v = 1, 2$. So $B_E^3 = B^2$ with $\alpha_\epsilon = (1, 1, 1, 1)$. The morphism $\text{Rep}_\alpha(E^\perp) \rightarrow \text{Rep}_{\alpha_\epsilon}(B^2)$ can be explicitly described as

$$\begin{cases} A_2 = F_3^{-1} A_3, \\ B_2 = B_3, \\ C_2 = F_3^{-1} C_3, \\ D_2 = D_3, \\ E_2 = E_3. \end{cases}$$

Consider the quiver B^4

with dimension vector $\alpha = (1, 1, 1, 1, 1, 2)$. Then there are ten exceptional representations left orthogonal to α . They are

$$0 \rightarrow P_6 \rightarrow P_u \oplus P_v \rightarrow E_{uv} \rightarrow 0,$$

where $\{u, v\} \subset \{1, 2, 3, 4, 5\}$. It is easy to check that $(E_{uv})_\alpha^{\text{reg}} = \text{Rep}_\alpha(B^4)$. Let $E = E_{45}$. To compute B_E^4 , we observe that $P_4, P_5 \in E^\perp$, $\tilde{\pi}_E(P_6) = P_4 \oplus P_5$, and $\tilde{\pi}_E(P_v) = P_6 \rightarrow P_5 \oplus P_4 \oplus P_v$ for $v = 1, 2, 3$. So $B_E^4 = B^3$ with $\alpha_\epsilon = (1, 1, 1, 1, 1)$. The morphism $\text{Rep}_\alpha(E^\perp) \rightarrow \text{Rep}_{\alpha_\epsilon}(B^3)$ can be explicitly described as

$$\begin{cases} A_3 = \det(A_4, D_4), \\ B_3 = \det(A_4, E_4), \\ C_3 = \det(B_4, D_4), \\ D_3 = \det(B_4, E_4), \\ E_3 = \det(C_4, E_4), \\ F_3 = \det(C_4, D_4). \end{cases}$$

Example 2.12. Consider the quiver $B^{4,1}$

with dimension vector $\alpha = (1, 1, 1, 1, 1, 2, 2)$. Then there are eighteen representations exceptional to α . The ones interesting to us are

$$\begin{aligned} 0 \rightarrow P_7 \rightarrow P_6 \rightarrow E_1 \rightarrow 0 \\ 0 \rightarrow P_6 \rightarrow P_5 \oplus P_4 \rightarrow E_2 \rightarrow 0 \end{aligned}$$

To compute $B_{E_1}^{4,1}$, we observe that $P_4, P_5, P_6 \in E_1^\perp$, $\tilde{\pi}_{E_1}(P_7) = P_6$, and $\tilde{\pi}_{E_1}(P_v) = P_7 \rightarrow P_6 \oplus P_v$ for $v = 1, 2, 3$. So $B_{E_1}^{4,1} = B^4$ with $\alpha_{e_1} = (1, 1, 1, 1, 1, 2)$. The morphism $\text{Rep}_\alpha(E_1^\perp) \rightarrow \text{Rep}_{\alpha_{e_1}}(B^4)$ can be explicitly described as

$$\begin{cases} A_4 = F_5^{-1}A_5, \\ B_4 = F_5^{-1}B_5, \\ C_4 = F_5^{-1}C_5, \\ D_4 = D_5, \\ E_4 = E_5. \end{cases}$$

We leave it to interested reader to verify that $B_{E_2}^{4,1}$ is also equal to B^4 and those are the only two among the eighteen representations.

Example 2.13. Consider quiver C_3^6 :

$$1 \xrightarrow{a} 2 \xrightleftharpoons[b]{c} 3$$

with dimension vector $\alpha = (1, 4, 3)$, then the only representation left exceptional to α is $E = (0, 3, 2)$. By computation, we have that $\pi_E^\vee(I_1) = I_1$, $\pi_E^\vee(I_2) = 4(3I_3 \rightarrow 2I_2)$, and $\pi_E^\vee(I_3) = 3I_3 \rightarrow 2I_2$. So $(C_3^6)_E$ is the four-arrow Kronecker quiver with $\alpha_e = (1, 1)$. Let us denote the four arrows by a_E, b_E, c_E, d_E . As a good exercise, one can check that $3I_3 \rightarrow 2I_2$ can be represented by the matrix $\begin{pmatrix} b & 0 & c \\ 0 & c & b \end{pmatrix}^T$, and that the morphism $\text{Rep}_\alpha(E^{\text{reg}}) \rightarrow \text{Mod}_{\alpha_e}(C_2^1)$ can be represented by $A_E = \det \begin{pmatrix} B & 0 & C \\ 0 & C & B \\ AB & 0 & 0 \end{pmatrix}$, $B_E = \det \begin{pmatrix} B & 0 & C \\ 0 & C & B \\ AC & 0 & 0 \end{pmatrix}$, $C_E = \det \begin{pmatrix} B & 0 & C \\ 0 & C & B \\ 0 & AB & 0 \end{pmatrix}$, $D_E = \det \begin{pmatrix} B & 0 & C \\ 0 & C & B \\ 0 & AC & 0 \end{pmatrix}$. The representations in $\mathcal{E}_\alpha$ have the following normal form: $A = (*, *, *, -1)$, $B = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix}$, $C = \begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & s \end{pmatrix}$. Plug in and we get the image of $\mathcal{E}_\alpha$ has the form

$$(2.1) \quad A_E = st^2, B_E = t^3, C_E = s^3, D_E = s^2t.$$

This example is taken from [8]. We will continue these examples later.

3. THE EXCEPTIONAL SET $\mathcal{E}_\alpha$

Definition 3.1. For any dimension vector γ , we define $\text{Hom}(k^\alpha, k^\beta)_\gamma$

$$= \{(M_1, N_1, \phi) \in \text{Gr} \begin{pmatrix} \alpha \\ \alpha - \gamma \end{pmatrix} \times \text{Gr} \begin{pmatrix} \beta \\ \gamma \end{pmatrix} \times \text{Hom}(k^\alpha, k^\beta) \mid \text{Ker } \phi = M_1, \text{Im } \phi = N_1\},$$

$$\begin{aligned} & \text{Hom}_Q(\alpha, \beta)_\gamma \\ &= \{(M, N, M_1, N_1, \phi) \in \text{Rep}_\alpha(Q) \times \text{Rep}_\beta(Q) \times \text{Hom}(k^\alpha, k^\beta)_\gamma \mid \phi \in \text{Hom}_Q(M, N)\}. \end{aligned}$$

Lemma 3.2. $q : \text{Hom}(k^\alpha, k^\beta)_\gamma \rightarrow \text{Gr}_{\alpha-\gamma}^\alpha \times \text{Gr}_\gamma^\beta$ is a principal GL_γ -bundle. In particular, $\text{Hom}(k^\alpha, k^\beta)_\gamma$ is smooth and irreducible.

$r : \text{Hom}_Q(\alpha, \beta)_\gamma \rightarrow \text{Hom}(k^\alpha, k^\beta)_\gamma$ is a vector bundle with fiber

$$\bigoplus_{a \in Q_1} (\text{Hom}(k^{\gamma(ta)}, k^{\gamma(ha)}) \oplus \text{Hom}(k^{(\beta-\gamma)(ta)}, k^{\beta(ha)}) \oplus \text{Hom}(k^{\alpha(ta)}, k^{(\alpha-\gamma)(ha)})).$$

In particular, $\text{Hom}_Q(\alpha, \beta)_\gamma$ is smooth and irreducible with

$$(3.1) \quad \dim(\text{Hom}_Q(\alpha, \beta)_\gamma) = \dim \text{Rep}_\alpha(Q) + \dim \text{Rep}_\beta(Q) + \langle \alpha, \beta \rangle - \langle \alpha - \gamma, \beta - \gamma \rangle.$$

Proof. (Sketch) For any $\iota \in \text{Hom}(k^\gamma, k^\alpha)$ injective and $\pi \in \text{Hom}(k^\beta, k^\gamma)$ surjective, define $V_{\iota\pi} = \{(M_1, N_1, \phi) \in \text{Hom}(k^\alpha, k^\beta)_\gamma \mid \pi\phi\iota \text{ is isomorphism}\}$ and $U_{\iota\pi} = \{(M_1, N_1) \in \text{Gr}_{\alpha-\gamma}^\alpha \times \text{Gr}_\gamma^\beta \mid k^\alpha = M_1 + \text{Im}(\iota), k^\beta = N_1 + \text{Ker}(\pi)\}$. Then $\{U_{\iota\pi}\}$ is an open cover of $\text{Gr}_{\alpha-\gamma}^\alpha \times \text{Gr}_\gamma^\beta$ and $\{V_{\iota\pi}\}$ is an open cover of $\text{Hom}(k^\alpha, k^\beta)_\gamma$ such that $V_{\iota\pi} = U_{\iota\pi} \times \text{GL}_\gamma$. Moreover, one can show that r is trivial over $V_{\iota\pi}$. $\square$

Now we assume that $\langle \alpha, \beta \rangle_Q = 0$. Let C be the subscheme of $\text{Rep}_\alpha(Q) \times \text{Rep}_\beta(Q)$ defined by $c(M, N) := \det \phi_N^M$ (1.2), so its reduced part is

$$C_{\text{red}} = \{(M, N) \in \text{Rep}_\alpha(Q) \times \text{Rep}_\beta(Q) \mid \text{hom}_Q(M, N) > 0\}.$$

Definition 3.3. We call the (non-trivial) general rank γ on any irreducible component of C a *fundamental rank* for (α, β) .

Lemma 3.4. All the irreducible components of C are parameterized by the fundamental ranks. We denote by C_γ the component with fundamental rank γ , then

$$(3.2) \quad \text{ext}_Q(C_\gamma) = \text{hom}_Q(C_\gamma) = 1 - \langle \alpha - \gamma, \beta - \gamma \rangle.$$

Proof. Let C_0 be irreducible component of C_{red} and γ be the general rank on C_0 . Consider the projection $p : \text{Hom}_Q(\alpha, \beta)_\gamma \rightarrow \text{Rep}_\alpha(Q) \times \text{Rep}_\beta(Q)$. $p(\text{Hom}_Q(\alpha, \beta)_\gamma)$ is irreducible and must equal to C_0 .

If $(M, N) \in C_\gamma$ is in general position, then a general element in $\text{Hom}_Q(M, N)$ has rank γ . But the fiber $p^{-1}(M, N)$ is $\{\phi \in \text{Hom}_Q(M, N) \mid \text{rank } \phi = \gamma\}$, so

$$\begin{aligned} \text{ext}_Q(C_\gamma) &= \text{hom}_Q(C_\gamma) = \dim p^{-1}(M, N) \\ &= \dim(\text{Hom}_Q(\alpha, \beta)_\gamma) - \dim(\text{Rep}_\alpha(Q) \times \text{Rep}_\beta(Q)) \\ &= 1 - \langle \alpha - \gamma, \beta - \gamma \rangle. \end{aligned}$$

$\square$

We denote the following three sets respectively by $\text{Rep}_{\gamma \hookrightarrow \alpha}(Q)$, $\text{Rep}_{\alpha \twoheadrightarrow \gamma}(Q)$, and $\text{Rep}_{\gamma \oplus \alpha - \gamma}(Q)$:

- $\{M \in \text{Rep}_\alpha(Q) \mid M \text{ has a } \gamma\text{-dimensional subrepresentation}\},$
- $\{M \in \text{Rep}_\alpha(Q) \mid M \text{ has a } \gamma\text{-dimensional quotient representation}\},$
- $\{M \in \text{Rep}_\alpha(Q) \mid M \text{ has a direct sum decomposition of dimension } \gamma \text{ and } \alpha - \gamma\},$

The following lemma is implied in the proof of [17, Theorem 2.1, 3.3].

Lemma 3.5. $\text{Rep}_{\gamma \rightarrow \alpha}(Q)$ is a closed irreducible subvariety of codimension equal to $\text{ext}_Q(\gamma, \alpha - \gamma)$ in $\text{Rep}_\alpha(Q)$; $\text{Rep}_{\gamma \oplus \alpha - \gamma}(Q)$ is irreducible of codimension equal to $\text{ext}_Q(\gamma, \alpha - \gamma) + \text{ext}_Q(\alpha - \gamma, \gamma)$ in $\text{Rep}_\alpha(Q)$.

Corollary 3.6. If $E \perp \alpha$, then the following are equivalent

- (1) E is left exceptional to α ;
- (2) ϵ is a fundamental rank for (ϵ, α) ;
- (3) $\text{ext}_Q(\epsilon, \alpha - \epsilon) = 1$, or equivalently $\text{hom}_Q(\epsilon, \alpha - \epsilon) = 0$;

In this case, the exceptional set $\mathcal{E}_\alpha$ is irreducible and $\text{hom}_Q(E, \mathcal{E}_\alpha) = 1$. Moreover, $\text{Rep}_{\epsilon \rightarrow \alpha}(Q) = \overline{\mathcal{E}_\alpha}$ and $\text{Rep}_{\alpha \rightarrow \epsilon}(Q) = \overline{\text{GL}_\alpha \cdot \tilde{\pi}_E(\mathcal{E}_\alpha)}$.

Proof. If $\mathcal{E}_\alpha$ is non-empty, then ϵ is clearly a general rank on $\text{GL}_\epsilon E \times \mathcal{E}_\alpha$. But $\text{GL}_\epsilon E$ is dense in $\text{Rep}_\epsilon(Q)$, so $\text{GL}_\epsilon E \times \mathcal{E}_\alpha$ has codimension one in $\text{Rep}_\epsilon(Q) \times \text{Rep}_\alpha(Q)$, and thus must be irreducible. Hence, ϵ is a fundamental rank for (ϵ, α) and $\mathcal{E}_\alpha$ is irreducible. Now each representation on $\mathcal{E}_\alpha$ has a subrepresentation of dimension ϵ , so $\text{ext}_Q(\epsilon, \alpha - \epsilon) = 1$. Conversely, if $\text{ext}_Q(\epsilon, \alpha - \epsilon) = 1$, then $\text{hom}_Q(\epsilon, \alpha - \epsilon) = 0$. Let M be a general representation in $\text{Rep}_{\epsilon \rightarrow \alpha}(Q)$. We can assume M/E is general in $\text{Rep}_{\alpha - \epsilon}(Q)$. We claim that $\text{Hom}_Q(E, M)$ contains solely one monomorphism, otherwise $\text{hom}_Q(E, M/E) > 0$ contradicting $\text{hom}_Q(\epsilon, \alpha - \epsilon) = 0$. So this monomorphism is indeed the universal homomorphism.

$\text{hom}_Q(E, \mathcal{E}_\alpha) = 1$ follows from the formula (3.2). $\text{Rep}_{\epsilon \rightarrow \alpha}(Q) = \overline{\mathcal{E}_\alpha}$ is evident from Lemma 3.5. So we can require the cokernel of universal homomorphism is in general position, and therefore $\text{GL}_\alpha \cdot \tilde{\pi}_E(\mathcal{E}_\alpha)$ is dense in $\text{Rep}_{\alpha \rightarrow \epsilon}(Q)$. $\square$

Example 3.7. It is possible that E is left orthogonal to α with $\dim_Q E < \alpha$, but E is not left exceptional to α . Consider a reflected quiver C_3^6 :

$$1 \rightrightarrows 2 \longrightarrow 3$$

with $\alpha = (2, 2, 1)$, then the only representation left orthogonal to α is $E = (1, 2, 0)$ (We take the reflection to make E on the left). However, $\alpha - \epsilon = (1, 0, 1)$ and $\text{Hom}_Q(E, S_1) = 1$, so $\text{hom}_Q(\epsilon, \alpha - \epsilon) = 1$. Moreover, one can check that the only fundamental rank for (ϵ, α) is $(1, 1, 0) \neq \epsilon$.

The proposition may be useful in Section 6.

Proposition 3.8. Suppose that for any dimension vector $\gamma < \alpha$, $\text{Rep}_{\alpha \rightarrow \epsilon}(Q) \not\subseteq \overline{\text{Rep}_{\gamma \oplus \alpha - \gamma}(Q)}$, then $\text{hom}_Q(\alpha - \epsilon, \epsilon) = 0$, so $\text{ext}_Q(\alpha - \epsilon, \epsilon) = -\langle \alpha - \epsilon, \epsilon \rangle_Q$.

Proof. The proof is just a slight variation of that of [16, Theorem 4.1]. Suppose that $\text{hom}_Q(\alpha - \epsilon, \epsilon) > 0$, then let γ be the general rank on $\text{Rep}_{\alpha - \epsilon}(Q) \times \text{Rep}_\epsilon(Q)$. We claim that either $\gamma = \alpha - \epsilon$ or $\gamma = \epsilon$. Suppose this is not the case. We take a general representations $L \in \text{Rep}_{\alpha - \epsilon}(Q)$ with a general morphism f to E . Let K, I, C be the (non-trivial) kernel, image, and cokernel, then we have an induced surjection $\text{Ext}_Q(C, L) \twoheadrightarrow \text{Ext}_Q(C, I)$, which corresponds to the following exact diagram of extensions:

$$\begin{array}{ccccccc} 0 & \longrightarrow & L & \xrightarrow{\iota'} & M & \longrightarrow & C \longrightarrow 0 \\ & & \downarrow f & & \downarrow f' & & \parallel \\ 0 & \longrightarrow & I & \xrightarrow{\iota} & E & \longrightarrow & C \longrightarrow 0, \end{array}$$

from which we can construct an exact sequence of representations

$$0 \longrightarrow L \xrightarrow{(f \ -\iota')} I \oplus M \xrightarrow{\begin{pmatrix} \iota' \\ f' \end{pmatrix}} E \longrightarrow 0.$$

This exact sequence cannot split, otherwise $I \oplus M = L \oplus E$ contradicts the uniqueness of decomposition. So the sequence corresponds to a general extension in $\text{Ext}_Q(E, L)$. This is because $\text{ext}_Q(\epsilon, \alpha - \epsilon) = 1$ and L, E are general. Then a general representation in $\text{Rep}_{\alpha \rightarrow \epsilon}(Q)$ has a decomposition of dimension γ and $\alpha - \gamma$, which contradicts our assumption.

Now we assume that $\gamma = \alpha - \epsilon$, then we have an exact sequence $0 \rightarrow L \rightarrow E \rightarrow C \rightarrow 0$. Apply $\text{Hom}_Q(-, E)$ to it, we get $0 = \text{Ext}_Q(E, E) \rightarrow \text{Ext}_Q(L, E) \rightarrow 0$, so $\text{ext}_Q(\alpha - \epsilon, \epsilon) = 0$, which also contradicts our assumption by Lemma 3.5. If $\gamma = \epsilon$, then a general $(\alpha - \epsilon)$ -dimensional representation has a $(\alpha - 2\epsilon)$ -dimensional subrepresentation, so $\text{ext}_Q(\alpha - 2\epsilon, \epsilon) = 0$. For a general $(\alpha - 2\epsilon)$ -dimensional representation K , let us consider the exact sequence $0 \rightarrow K \rightarrow K \oplus E \rightarrow E \rightarrow 0$. Apply $\text{Hom}_Q(-, E)$ to it, then we get

$$0 = \text{Ext}_Q(E, E) \rightarrow \text{Ext}_Q(K \oplus E, E) \rightarrow \text{Ext}_Q(K, E) = 0.$$

So $\text{ext}_Q(\alpha - \epsilon, \epsilon) = 0$ and we get the same contradiction. $\square$

4. SOME HOMOLOGICAL ALGEBRA

Lemma 4.1. *Let M be a E -regular representation and $0 \rightarrow P_1 \rightarrow P_0 \rightarrow M \rightarrow 0$ be a projective resolution, then $0 \rightarrow \tilde{\pi}_E(P_1) \rightarrow \tilde{\pi}_E(P_0) \rightarrow \tilde{\pi}_E(M) \rightarrow 0$ is a projective resolution in $E^\perp$. In particular, $\text{Ext}_{Q_E}(\pi_E(M), -) = \text{Ext}_Q(M, -)$ on $E^\perp$.*

Proof. We need to show that $\tilde{\pi}_E(P_1) \rightarrow \tilde{\pi}_E(P_0)$ is injective. If not, let K be the kernel, which must be projective in $E^\perp$. Since M, P_1, P_0 are all E -regular, we see that the dimension of K is a multiple of ϵ , which is impossible. The last statement is clear from the proof of the next lemma. $\square$

Lemma 4.2. *For any $M \in \text{Mod}(Q)$, $\text{Ext}_{Q_E}(\pi_E(M), -) \subseteq \text{Ext}_Q(M, -)$ on $E^\perp$. So $M \perp N$ implies $\pi_E(M) \perp N$ for $N \in E^\perp$.*

Proof. Take a projective resolution of $M : 0 \rightarrow P_1 \rightarrow P_0 \rightarrow M \rightarrow 0$, then $\pi_E(P_1) \rightarrow \pi_E(P_0) \rightarrow \pi_E(M) \rightarrow 0$ is exact. Let us look at the following diagram.

$$\begin{array}{ccccccc} 0 & \longrightarrow & \text{Hom}_Q(M, N) & \longrightarrow & \text{Hom}_Q(P_0, N) & \longrightarrow & \text{Hom}_Q(P_1, N) \longrightarrow \text{Ext}_Q(M, N) \twoheadrightarrow 0 \\ & & \parallel & & \parallel & & \parallel \\ 0 & \twoheadrightarrow & \text{Hom}_{Q_E}(\pi_E(M), N) & \twoheadrightarrow & \text{Hom}_{Q_E}(\pi_E(P_0), N) & \twoheadrightarrow & \text{Hom}_{Q_E}(\pi_E(P_1), N) \longrightarrow E \longrightarrow 0 \end{array}$$

Since $N \in E^\perp$, the adjunction property give the first three vertical isomorphisms, which implies the last isomorphism. Clearly $\text{Ext}_{Q_E}(\pi_E(M), N)$ is a subspace of E . $\square$

In fact, we will use frequently the dual of the above lemma, so we record it here for reader's convenience.

Lemma 4.2*. *For any $N \in \text{Mod}(Q)$, $\text{Ext}_{Q_E}(-, \pi_E^\vee(N)) \subseteq \text{Ext}_Q(-, N)$ on $E^\perp$. So $M \perp N$ implies $M \perp \pi_E^\vee(N)$ for $M \in E^\perp$.*

Let M be a E -regular representation and $r_M : M \rightarrow \tilde{\pi}_E(M)$ be the universal map, then it induces

$$r_M^e : \text{Ext}_Q(M, M) \rightarrow \text{Ext}_Q(M, \tilde{\pi}_E(M)) \cong \text{Ext}_{Q_E}(\pi_E(M), \pi_E(M)).$$

Consider the morphism $\pi_{E,\alpha} : \text{Mod}_\alpha(E^{\text{reg}}) \rightarrow \text{Mod}_{\alpha_E}(Q_E)$ induced by π_E as in Lemma 2.8. It is well-known that the tangent space of $\text{Mod}_\alpha(Q)$ is isomorphic to $\text{Ext}_Q(M, M)$ [5, Lemma 2.2]. Note that $\text{Mod}_\alpha(E^{\text{reg}})$ is open in $\text{Mod}_\alpha(Q)$, then the following is clear.

Proposition 4.3. *The tangent map of $\pi_{E,\alpha}$ at $M \in \text{Mod}_\alpha(E^{\text{reg}})$ is r_M^e . In particular, the kernel of r_M^e is isomorphic to the tangent space $\mathcal{T}_M(\pi_{E,\alpha}^{-1}(\pi_E(M)))$.*

The interested readers can verify that all the tangent maps in Example 2.11, 2.12, and 2.13 at $M \notin E^\perp$ have a one-dimensional kernel.

5. A FUNCTORIAL CONSTRUCTION

Let α be a non-isotropic imaginary Schur root and $\sigma_\beta = -\langle \cdot, \beta \rangle_Q$ be a weight. We assume that $\text{Rep}_\alpha(Q)$ contains a σ_β -stable representation. Let E be an exceptional representation with $\dim_Q E = \epsilon$ and we assume it is left orthogonal to α . Note that $\text{Rep}_\alpha(E^\perp) = \text{Rep}_\alpha^{\sigma_\beta \cdot \text{ss}}(Q)$ because $\text{GL}_\epsilon E$ is dense in $\text{Rep}_\epsilon(Q)$. We denote by $\text{Rep}_\alpha^{\sigma_\beta \cdot \text{ss}}(Q) \cap E^\perp$ (resp. $\text{Rep}_\alpha^{\sigma_\beta \cdot \text{st}}(Q) \cap E^\perp$) by $\text{Rep}_\alpha^{\sigma_\beta \cdot \text{ss}}(E^\perp)$ (resp. $\text{Rep}_\alpha^{\sigma_\beta \cdot \text{st}}(E^\perp)$). It follows from the dual of Lemma 4.2 that α_ϵ is $\sigma_{\beta_E^\vee}$ -semi-stable.

Definition 5.1. A representation $M \in \text{Rep}_\alpha^{\sigma_\beta \cdot \text{ss}}(Q)$ is called E -effective if $\pi_E(M) \in \text{Mod}_{\alpha_\epsilon}^{\sigma_{\beta_E^\vee} \cdot \text{ss}}$. Clearly, being E -effective is an open condition. We denote the set of all E -effective σ_β -semi-stable α -dimensional representations by $\text{Rep}_\alpha^{\sigma_{\beta_E^\vee} \cdot \text{ss}}(Q)$ and all E -effective σ_β -unstable representations in $\text{Rep}_\alpha(E^\perp)$ by $\text{Rep}_\alpha^{\sigma_{\beta_E^\vee} \cdot \text{us}}(E^\perp)$.

Lemma 5.2. *If $M \in \text{Rep}_\alpha(E^\perp)$ is σ_β -(semi-)stable, then $\pi_E(M)$ is $\sigma_{\beta_E^\vee}$ -(semi-)stable. In particular, α_ϵ is $\sigma_{\beta_E^\vee}$ -stable.*

Proof. Let $M_1 \in \text{Mod}(Q_E)$ be a quotient representation of $\pi_E(M)$, then we have that $\sigma_{\beta_E^\vee}(\dim_{Q_E} M_1) \geq \sigma_\beta(\dim_Q \iota_E(M_1))$ by the dual of Lemma 4.2. Since ι_E is an exact embedding, $\iota_E(M_1)$ is also a quotient representation of $\iota_E \pi_E(M)$. But $\iota_E \pi_E(M) = M$ because $M \in E^\perp$. Now everything follows from King's criterion (Lemma 1.1). $\square$

Remark 5.3. In general, σ_β -unstable points in $\text{Rep}_\alpha(E^\perp)$ may become $\sigma_{\beta_E^\vee}$ -semi-stable under π_E . According to Lemma 2.10, this is equivalent to say that $\sigma_{\beta_E^\vee}$ -semi-stable points may become unstable under ι_E . The following lemma is an easy consequence of King's criterion.

Lemma 5.4. *A σ_β -unstable representation $M \in \text{Rep}_\alpha(E^\perp)$ is E -effective if and only if there is no subrepresentation (resp. quotient) M_1 of M such that $M_1 \in E^\perp$ and $\sigma_\beta(\dim_Q M_1) > 0$ (resp. $\sigma_\beta(\dim_Q M_1) < 0$).*

Now we turn to the inverse functor ι_E . Let p be the projection:

$$\text{Rep}_\alpha(E^\perp) \cong \text{GL}_\alpha \times_{\text{GL}_{\alpha_\epsilon}} \text{Rep}_{\alpha_\epsilon}(Q_E) \rightarrow \text{Rep}_{\alpha_\epsilon}(Q_E)$$

and $\text{Rep}_{\alpha_\epsilon}^{\sigma_{\beta_E^\vee} \cdot \text{ss}}(Q_E)$ be the open set $p(\text{Rep}_\alpha^{\sigma_\beta \cdot \text{ss}}(E^\perp))$ in $\text{Rep}_{\alpha_\epsilon}(Q_E)$. By definition, it consists exactly of all representations M such that $\iota_E(M)$ is σ_β -semi-stable. We also denote $p(\text{Rep}_\alpha^{\sigma_\beta \cdot \text{st}}(E^\perp))$ and $p(\text{Rep}_\alpha^{\sigma_\beta \cdot \text{us}}(E^\perp))$ by $\text{Rep}_{\alpha_\epsilon}^{\sigma_\beta \cdot \text{st}}(Q_E)$ and $\text{Rep}_{\alpha_\epsilon}^{\sigma_\beta \cdot \text{su}}(Q_E)$

respectively. Note that $\text{Rep}_{\alpha_\epsilon}^{\sigma_\beta \cdot \text{su}}(Q_E)$ consists exactly all representations $M \in \text{Rep}_{\alpha_\epsilon}^{\sigma_{\beta_E}^\vee \cdot \text{ss}}(Q_E)$ such that $\iota_E(M)$ is σ_β -unstable, so it is closed in $\text{Rep}_{\alpha_\epsilon}^{\sigma_{\beta_E}^\vee \cdot \text{ss}}(Q_E)$.

We give a useful criterion on when $\text{Rep}_{\alpha_\epsilon}^{\sigma_\beta \cdot \text{ss}}(Q_E) = \text{Rep}_{\alpha_\epsilon}^{\sigma_{\beta_E}^\vee \cdot \text{ss}}(Q_E)$, i.e., ι_E preserves (semi-)stable points. At certain points below, we may assume that σ_β is a $E^\vee$ -regular weight, that is, $(n\beta)_E^\vee = n\beta_\epsilon^\vee$ for any $n \in \mathbb{N}$. Equivalently, for a general $N \in \text{Rep}_{n\beta}(Q)$, the universal homomorphism $N \rightarrow \tau E^h$ is surjective. We also note that under this assumption, $\langle \epsilon, \beta \rangle = 0$ would imply $E \perp \beta$, because $E \perp \tilde{\pi}_E^\vee(N)$.

Remark 5.5. We want to point out this is really not a big assumption. As an easy consequence of Generalized Fulton's Conjecture [7, Theorem 7.16], α is strictly $\sigma_{\tau\epsilon}$ -semi-stable, so $\tau\epsilon$ must lie on the boundary of the cone $\Sigma_\alpha(Q)$. In fact, in many cases it is an extremal ray of $\Sigma_\alpha(Q)$, then N must map onto τE^h .

Proposition 5.6. *Assume that σ_β is a $E^\vee$ -regular weight, then $\pi_E^\vee(\text{Rep}_\beta(Q))$ contains a dense subset of $\text{Rep}_{\beta_E}^\vee(Q_E)$ if and only if*

- (i) $\langle \epsilon, \beta \rangle_Q \leq 0$, or
- (ii) $\langle \epsilon, \beta \rangle_Q > 0$ and $\text{ext}_Q(\tau\epsilon, \beta) = 0$.

In these cases, ι_E preserves semi-stable points.

Proof. If $-m = \langle \epsilon, \beta \rangle_Q \leq 0$, then $\beta = \tilde{\beta}_\epsilon^\vee + m(\tau\epsilon)$, and $E \perp \tilde{\beta}_\epsilon^\vee$. Consider the representations of form $M \oplus m(\tau E)$, where $M \in \text{Rep}_{\tilde{\beta}_\epsilon^\vee}(E^\perp)$. Clearly $\tilde{\pi}_E^\vee(M \oplus m(\tau E)) = M$, so $\pi_E^\vee(\text{Rep}_\beta(Q))$ contains $\text{Rep}_{\beta_E}^\vee(Q_E)$.

If $\langle \epsilon, \beta \rangle_Q > 0$, then $\text{hom}_Q(\beta, \tau\epsilon) > 0$. In this case, one can verify by [5, Lemma 2.3.ii] that $\text{ext}_Q(\tau\epsilon, \beta) = 0$ is a necessary and sufficient condition for $\pi_E^\vee(\text{Rep}_\beta(Q))$ containing a dense subset of $\text{Rep}_{\beta_E}^\vee(Q_E)$.

Now if $M \in \text{Rep}_{\alpha_\epsilon}(Q_E)$ is $\sigma_{\beta_\epsilon^\vee}$ -semi-stable, then there is some general representation $N \in \text{Rep}_{n\beta_\epsilon^\vee}(Q_E)$ such that $M \perp N$. Since we assume that σ_β is a $E^\vee$ -regular weight, $N = \pi_E^\vee(\tilde{N})$ for some $\tilde{N} \in \text{Rep}_{n\beta}(Q)$. By the adjointness, $\text{Hom}_Q(\iota_E(M), \tilde{N}) = \text{Hom}_{Q_E}(M, N) = 0$. Since $\sigma_\beta(\alpha) = 0$, $\iota_E(M) \perp \tilde{N}$ and thus $\iota_E(M)$ is σ_β -semi-stable. $\square$

Definition 5.7. A weight σ_β is called *weakly $\mathcal{E}_\alpha$ -effective* if $\mathcal{E}_\alpha \cap \text{Rep}_\alpha^{\sigma_{\beta_E}^\vee \cdot \text{ss}}(Q)$ is non-empty. It is called *$\mathcal{E}_\alpha$ -effective* if in addition $\langle \epsilon, \beta \rangle_Q > 0$.

Note that for any $M \in \mathcal{E}_\alpha$, E is a subrepresentation of M . So if σ_β is weakly (resp. strongly) $\mathcal{E}_\alpha$ -effective, then at least we have that $\langle \epsilon, \beta \rangle_Q \geq 0$ (resp. $\langle \epsilon, \beta \rangle_Q > 0$). This and the following lemma justifies the seemingly unnatural condition $\langle \epsilon, \beta \rangle_Q > 0$. It is possible that there exists weakly $\mathcal{E}_\alpha$ -effective weight but no $\mathcal{E}_\alpha$ -effective weight, see Example 5.20.

$$\begin{aligned} \text{Let } \mathcal{E}_\alpha^{\sigma_\beta} &:= \{M \in \mathcal{E}_\alpha \cap \text{Rep}_\alpha^{\sigma_\beta \cdot \text{ss}}(Q) \mid \tilde{\pi}_E(M) \in \text{Mod}_\alpha^{\sigma_{\beta_E}^\vee \cdot \text{us}}(E^\perp)\} \\ &= \{M \in \mathcal{E}_\alpha \cap \text{Rep}_\alpha^{\sigma_{\beta_E}^\vee \cdot \text{ss}}(Q) \mid \tilde{\pi}_E(M) \in \text{Mod}_\alpha^{\sigma_\beta \cdot \text{un}}(Q)\} \end{aligned}$$

Lemma 5.8.

- (i) *If $\langle \epsilon, \beta \rangle_Q > 0$, then $M \in \mathcal{E}_\alpha$ implies $\tilde{\pi}_E(M)$ is σ_β -unstable. In particular, $\mathcal{E}_\alpha^{\sigma_\beta} = \mathcal{E}_\alpha \cap \text{Rep}_\alpha^{\sigma_{\beta_E}^\vee \cdot \text{ss}}(Q)$.*
- (ii) *If σ_β is $E^\vee$ -regular and $\mathcal{E}_\alpha^{\sigma_\beta}$ is non-empty, then $\langle \epsilon, \beta \rangle_Q > 0$.*

Hence, the additional condition $\langle \epsilon, \beta \rangle_Q > 0$ can be replaced by $\mathcal{E}_\alpha^{\sigma_\beta} = \mathcal{E}_\alpha \cap \text{Rep}_\alpha^{\sigma_{\beta_E}^\vee \cdot \text{ss}}(Q)$ or $\mathcal{E}_\alpha^{\sigma_\beta}$ is non-empty when σ_β is $E^\vee$ -regular.

Proof. (i) Let us look at the second construction of Lemma 2.1. Since E^h is a subrepresentation of M and $\sigma_\beta(\epsilon) < 0$, $\sigma_\beta(\dim_Q(M'')) > 0$. But M'' is a subrepresentation of $\tilde{\pi}_E(M)$, so $\tilde{\pi}_E(M)$ is σ_β -unstable.

(ii) Pick a representation $M \in \mathcal{E}_\alpha^{\sigma_\beta}$, then by definition and Proposition 5.6, $\tilde{\pi}_E(M)$ is $\sigma_{\tau\epsilon}$ and $\sigma_{\tilde{\beta}_\epsilon^\vee}$ semi-stable but σ_β -unstable. So there is a subrepresentation L of M with $\dim L = \gamma$ such that $\sigma_\beta(\gamma) > 0$. Then $\sigma_{\tilde{\beta}_\epsilon^\vee}(\gamma) = \sigma_\beta(\gamma) + \langle \epsilon, \beta \rangle_Q \sigma_{\tau\epsilon}(\gamma) \leq 0$ implies that $\langle \epsilon, \beta \rangle_Q > 0$. $\square$

Corollary 5.9. *Let $q_E : \text{Rep}_{\alpha_\epsilon}^{\sigma_{\beta_E^\vee} \cdot \text{ss}}(Q_E) \rightarrow \text{Mod}_{\alpha_\epsilon}^{\sigma_{\beta_E^\vee}}(Q_E)$ be the GIT quotient map.*

- (i) $\text{Rep}_{\alpha_\epsilon}^{\sigma_{\beta_E^\vee} \cdot \text{ss}}(Q) = \text{Rep}_{\alpha_\epsilon}^{\sigma_\beta \cdot \text{ss}}(E^\perp) \amalg (\mathcal{E}_\alpha \cap \text{Rep}_{\alpha_\epsilon}^{\sigma_{\beta_E^\vee} \cdot \text{ss}}(Q));$
- (ii) $\text{Mod}_{\alpha_\epsilon}^{\sigma_{\beta_E^\vee}}(Q_E) = q_E(\text{Rep}_{\alpha_\epsilon}^{\sigma_\beta \cdot \text{ss}}(Q_E)) \amalg q_E(\text{Rep}_{\alpha_\epsilon}^{\sigma_\beta \cdot \text{su}}(Q_E)).$

Proof. (i) is an easy consequence of Lemma 5.2 and definitions. For (ii), by definition we already have that $\text{Rep}_{\alpha_\epsilon}^{\sigma_{\beta_E^\vee} \cdot \text{ss}}(Q_E) = \text{Rep}_{\alpha_\epsilon}^{\sigma_\beta \cdot \text{ss}}(Q_E) \amalg \text{Rep}_{\alpha_\epsilon}^{\sigma_\beta \cdot \text{su}}(Q_E)$. Let V_1, V_2 be two disjoint sets in $\text{Rep}_{\alpha_\epsilon}^{\sigma_\beta \cdot \text{ss}}(Q_E)$ and $\text{Rep}_{\alpha_\epsilon}^{\sigma_\beta \cdot \text{su}}(Q_E)$ respectively. We need to show that $\overline{V}_1$ and $\overline{V}_2$ are disjoint. By definition $p^{-1}(V_1)$ and $p^{-1}(V_2)$ are two disjoint sets in $\text{Rep}_\alpha^{\sigma_\beta \cdot \text{ss}}(E^\perp)$ and $\text{Rep}_\alpha^{\sigma_\beta \cdot \text{us}}(E^\perp)$ respectively. Their closures must be also disjoint because one consists of semi-stable points while the other consists of unstable points. Since $\overline{V}_i = p(p^{-1}(V_i))$, $\overline{V}_1$ and $\overline{V}_2$ are disjoint. $\square$

Let $q : \text{Rep}_\alpha^{\sigma_\beta \cdot \text{ss}}(Q) \rightarrow \text{Mod}_\alpha^{\sigma_\beta}(Q)$ be the GIT quotient map. [13, Proposition 5.2] implies the map q is the composition of two quotient maps $\hat{q} : \text{Rep}_\alpha^{\sigma_\beta \cdot \text{ss}}(Q) \rightarrow \text{Mod}_\alpha^{\sigma_\beta \cdot \text{ss}}(Q)$ and $\tilde{q} : \text{Mod}_\alpha^{\sigma_\beta \cdot \text{ss}}(Q) \rightarrow \text{Mod}_\alpha^{\sigma_\beta}(Q)$. Similarly, q_E is the composition of $\hat{q}_E$ and $\tilde{q}_E$.

Theorem 5.10. *The functor π_E induces a birational transformation*

$$\varphi_E : \text{Mod}_\alpha^{\sigma_\beta}(Q) \dashrightarrow \text{Mod}_{\alpha_\epsilon}^{\sigma_{\beta_E^\vee}}(Q_E),$$

whose fundamental set lies outside $q(\text{Rep}_{\alpha_\epsilon}^{\sigma_{\beta_E^\vee} \cdot \text{ss}}(Q))$. It maps $q(\text{Rep}_\alpha^{\sigma_\beta \cdot \text{ss}}(E^\perp))$ isomorphically onto $q_E(\text{Rep}_{\alpha_\epsilon}^{\sigma_\beta \cdot \text{ss}}(Q_E))$ and maps $q(\overline{\mathcal{E}_\alpha^{\sigma_\beta}})$ onto the closed set $\tilde{q}_E \pi_E(\mathcal{E}_\alpha^{\sigma_\beta})$.

Proof. By Lemma 2.8, we have already got a morphism from $\text{Rep}_\alpha(E^\perp) \amalg \mathcal{E}_\alpha$ to the moduli stack $\text{Mod}_{\alpha_\epsilon}(Q_E)$. By definition this morphism descends to $\text{Rep}_{\alpha_\epsilon}^{\sigma_{\beta_E^\vee} \cdot \text{ss}}(Q) \rightarrow \text{Mod}_{\alpha_\epsilon}^{\sigma_{\beta_E^\vee}}(Q_E)$. It is clearly constant on the orbit, so we use the fact that q is a categorical quotient to obtain a morphism $q(\text{Rep}_{\alpha_\epsilon}^{\sigma_{\beta_E^\vee} \cdot \text{ss}}(Q)) \rightarrow \text{Mod}_{\alpha_\epsilon}^{\sigma_{\beta_E^\vee}}(Q_E)$. Apply a similar argument to the functor ι_E , we get another morphism $q_E(\text{Rep}_{\alpha_\epsilon}^{\sigma_\beta \cdot \text{ss}}(Q_E)) \rightarrow \text{Mod}_\alpha^{\sigma_\beta}(Q)$. This is a rational inverse of φ_E because the property of ι_E ensure it maps $q_E(\text{Rep}_{\alpha_\epsilon}^{\sigma_\beta \cdot \text{ss}}(Q_E))$ isomorphically onto its image, which is $q(\text{Rep}_\alpha^{\sigma_\beta \cdot \text{ss}}(E^\perp))$ by Lemma 2.10 and Corollary 5.9.(i). Clearly, φ_E maps $q(\overline{\mathcal{E}_\alpha^{\sigma_\beta}})$ onto the closed set $\tilde{q}_E \pi_E(\mathcal{E}_\alpha^{\sigma_\beta})$.

The situation is depicted in the following diagram:

$$\begin{array}{ccccc} \text{Rep}_\alpha^{\sigma_\beta \cdot \text{ss}}(Q) & \xrightarrow{q} & \text{Mod}_\alpha^{\sigma_\beta}(Q) & \longleftarrow & \text{Rep}_{\alpha_\epsilon}^{\sigma_\beta \cdot \text{ss}}(Q_E) \\ \uparrow & & \uparrow \varphi_E^{-1} \quad \downarrow \varphi_E & & \downarrow \\ \text{Rep}_{\alpha_\epsilon}^{\sigma_{\beta_E^\vee} \cdot \text{ss}}(Q) & \longrightarrow & \text{Mod}_{\alpha_\epsilon}^{\sigma_{\beta_E^\vee}}(Q_E) & \xleftarrow{q_E} & \text{Rep}_{\alpha_\epsilon}^{\sigma_{\beta_E^\vee} \cdot \text{ss}}(Q_E) \end{array}$$

$\square$

Remark 5.11. Moreover, if

$$(5.1) \quad \text{Mod}_{\alpha}^{\sigma_{\beta}}(Q) \setminus q(\text{Rep}_{\alpha}^{\sigma_{\beta} \cdot \text{ss}}(E^{\perp})) \subseteq q(\mathcal{E}_{\alpha} \cap \text{Rep}_{\alpha}^{\sigma_{\beta}^{\vee} \cdot \text{ss}}(Q)),$$

then Corollary 5.9.(i) implies that φ_E is a morphism. If in addition the following two equivalent conditions are satisfied

$$(5.2) \quad q(\text{Rep}_{\alpha}^{\sigma_{\beta}^{\vee} \cdot \text{us}}(Q)) \subseteq \tilde{q}\tilde{\pi}_E(\mathcal{E}_{\alpha}^{\sigma_{\beta}}) \quad \text{or} \quad q_E(\text{Rep}_{\alpha_{\epsilon}}^{\sigma_{\beta} \cdot \text{su}}(Q_E)) \subseteq \tilde{q}_E\pi_E(\mathcal{E}_{\alpha}^{\sigma_{\beta}}),$$

then Corollary 5.9.(ii) implies that φ_E is surjective, and only contracts $q(\overline{\mathcal{E}_{\alpha}^{\sigma_{\beta}}})$ to $\tilde{q}_E\pi_E(\mathcal{E}_{\alpha}^{\sigma_{\beta}})$. The contraction may not be strict in the sense that the generic fiber can be zero-dimensional. In this generality, we cannot say too much on this contraction. However, we will see in the next section that the essential case is the blow-up of $\text{Mod}_{\alpha_{\epsilon}}^{\sigma_{\beta}^{\vee}}(Q_E)$ along $\tilde{q}_E\pi_E(\mathcal{E}_{\alpha}^{\sigma_{\beta}})$.

Recall our notation that $\beta^{\epsilon} = \iota_{\epsilon}(\beta)$, so $\pi_{\epsilon}(\beta^{\epsilon}) = \beta$.

Corollary 5.12. *In the situation (i) or (ii) of Proposition 5.6, the birational transformation φ_E is an isomorphism. In particular, if α, β are dimension vectors of Q_E such that $E \perp \alpha^{\epsilon}$ and $E \perp \beta^{\epsilon}$, then $\mathcal{M}_{\alpha}^{\sigma_{\beta}}(Q_E) \cong \mathcal{M}_{\alpha^{\epsilon}}^{\sigma_{\beta^{\epsilon}}}(Q)$.*

Motivated by Lemma 5.8, Theorem 5.10, and Corollary 5.12, we make the following definition:

Definition 5.13. The *core* $\Sigma_{\alpha}^{\heartsuit}(Q)$ of the G -ample cone $\Sigma_{\alpha}(Q)$ is the subcone defined by $\langle \epsilon, \cdot \rangle_Q > 0$ for all real roots ϵ left orthogonal to α ; and $\langle \cdot, \epsilon \rangle_Q < 0$ for all real roots ϵ right orthogonal to α . Its boundary $\partial\Sigma_{\alpha}^{\heartsuit}(Q)$ is called the *shell* of the core. In practice, a more useful definition is the *weak core* if we add the restriction $\epsilon < \alpha$.

Problem 5.14. Are there only finitely many real roots orthogonal to α ?

For a weight σ_{β} on the boundary $\partial\Sigma_{\alpha}^{\heartsuit}(Q)$, there usually exists strictly σ_{β} -semi-stable points. If there is no strictly σ_{β} -semi-stable points, then by Lemma 2.10 and Proposition 5.6 the whole C_{τ_E} consists of unstable points. So the *null-cone* has codimension one, which is quite rare considering α is a non-isotropic imaginary Schur root. So basically the boundary consists of a subset of *walls* in the sense of variational GIT theory [4, Definition 3.3.1]. Here we give it a special name “shell” to stress its importance in the quiver setting. From the view of Corollary 5.12, the birational transformation φ_E is just a special type of *wall-crossing*.

Lemma 5.15. *If the anti-canonical weight $\sigma_{ac} = -\langle \cdot, \alpha + \tau\alpha \rangle$ is $E^{\vee}$ -regular, then $\sigma_{ac_{\epsilon}^{\vee}}$ is the anti-canonical weight for $\text{Rep}_{\alpha_{\epsilon}}(Q_E)$.*

Proof. We need to verify that $\pi_{\epsilon}^{\vee}(\alpha + \tau\alpha) = \pi_{\epsilon}(\alpha) + \tau_{Q_E}(\pi_{\epsilon}(\alpha))$. But this is clear from the formula $\tau_{Q_E} = \pi_{\epsilon}^{\vee}\tau$. $\square$

Example 5.16. (Example 2.11 continued)

Let us consider the anti-canonical weight for $\text{Rep}_{\alpha}(B^1)$, i.e., $\sigma_{\beta} = (2, 1, -3)$, then σ_{β} is $\mathcal{E}_{\alpha}$ -effective. One can verify that $\epsilon = (1, 0, 1)$ is an extremal ray of the cone $\Sigma_{\alpha}(B^1)$, so σ_{β} is a $E^{\vee}$ -regular weight and $\sigma_{\beta_{\epsilon}^{\vee}} = (3, -3)$. It is clear that $\text{Mod}_{\alpha_{\epsilon}}^{\sigma_{\beta_{\epsilon}^{\vee}}}(\Theta_3)$ is the projective plane $\mathbb{P}^2$. Since there is no strictly semi-stable points in $\text{Rep}_{\alpha}(B^1)$, $\text{Mod}_{\alpha}^{\sigma_{\beta}}(B^1)$ is smooth. Elements in $\text{Rep}_{\alpha}^{\sigma_{\beta}^{\vee} \cdot \text{us}}(B^1)$ satisfy that $a_1 = b_1 = 0, c_1 \neq 0$, so $\pi_E(\text{Rep}_{\alpha}^{\sigma_{\beta}^{\vee} \cdot \text{us}}(B^1))$ is a single point N_1 represented by

$\{a = b = 0; c = 1\}$, which is exactly $\pi_E(\mathcal{E}_\alpha^{\sigma_\beta})$. Now by Theorem 5.10 and its remark, the birational morphism $\varphi_E : \text{Mod}_\alpha^{\sigma_\beta}(B^1) \rightarrow \text{Mod}_{\alpha_\epsilon}^{\sigma_{\beta^\vee}}(\Theta_3)$ contracts the curve $q(\mathcal{E}_\alpha^{\sigma_\beta})$ to a point N_1 . So by the Castelnuovo's criterion ([10, Theorem 5.7]) the curve must be a -1 -curve and φ_E is the blow-up at N_1 . This can also be seen from Theorem 6.3 later. It is clear from Corollary 5.12 that the chambers of $\tau^{-1}\Sigma_\alpha(B^3)$ can be described as follows: the core in red gives the blow-up at one point while the dark part gives $\mathbb{P}^2$.

Let us consider the anti-canonical weight for $\text{Rep}_\alpha(B^2)$, i.e., $\sigma_\beta = (2, 2, -1, -3)$, then σ_β is $\mathcal{E}_\alpha$ -effective for $E = E_2$. One can verify that $\epsilon = (0, 1, 0, 1)$ is an extremal ray of the cone $\Sigma_\alpha(B^2)$, so σ_β is a $E^\vee$ -regular weight and $\sigma_{\beta^\vee} = (2, 1, -3)$. For the same reason, $\text{Mod}_\alpha^{\sigma_\beta}(B^2)$ is smooth. Elements in $\text{Rep}_{\alpha^{\sigma_{\beta^\vee} \cdot \text{us}}}(B^2)$ satisfy that $b_2 = d_2 = 0$ and $a_2 = c_2 = e_2 \neq 0$, so $\pi_E(\text{Rep}_{\alpha^{\sigma_{\beta^\vee} \cdot \text{us}}}(B^2))$ is a single point N_2 represented by $\{b_1 = d_1 = 0; a_1 = c_1 = 1\}$, which is exactly $\pi_E(\mathcal{E}_\alpha^{\sigma_\beta})$. By Theorem 5.10 and its remark, the birational morphism $\varphi_E : \text{Mod}_\alpha^{\sigma_\beta}(B^2) \rightarrow \text{Mod}_{\alpha_\epsilon}^{\sigma_{\beta^\vee}}(B^1)$ is the blow-up at N_2 . Note that $\varphi_E(N_2) \in E(B^1)^\perp$, so it does not lie on the -1 -curve of $\text{Mod}_\alpha^{\sigma_\beta}(B^1)$. Hence $\text{Mod}_\alpha^{\sigma_\beta}(B^2)$ is the blow-up of $\mathbb{P}^2$ at two general points. We leave to interested readers to check that for $E = E_3$, $\varphi_E : \text{Mod}_\alpha^{\sigma_\beta}(B^2) \rightarrow \text{Mod}_{\alpha_\epsilon}^{\sigma_{\beta^\vee}}(\Theta_{2,2})$ is the blow-up of $\mathbb{P}^1 \times \mathbb{P}^1$ at one point. Using Corollary 5.12, one can easily verify that the chambers of $\tau^{-1}\Sigma_\alpha(B^3)$ can be described as follows: the red core, and yellow, blue, green parts gives the blow-up at two general points, the blow-up at one point, $\mathbb{P}^1 \times \mathbb{P}^1$, and $\mathbb{P}^2$ respectively.

Let us consider the anti-canonical weight for $\text{Rep}_\alpha(B^3)$, i.e., $\sigma_\beta = (2, 2, 2, -3, -3)$, then $\mathcal{E}_\alpha$ -effective for $E = E_{35}$. One can verify that $\epsilon = (0, 0, 1, 1, 0)$ is an extremal ray of the cone $\Sigma_\alpha(B^3)$, so σ_β is a $E^\vee$ -regular weight and $\sigma_{\beta^\vee} = (2, 2, -1, -3)$. For

the same reason, $\text{Mod}_\alpha^{\sigma_\beta}(B^3)$ is smooth. Elements in $\text{Rep}_\alpha^{\sigma_{\beta_\epsilon}^\vee \cdot \text{us}}(B^3)$ satisfy that $b_3 = d_3 = 0$ and $a_3 = c_3 = e_3 = f_3 \neq 0$, so $\pi_E(\text{Rep}_\alpha^{\sigma_{\beta_\epsilon}^\vee \cdot \text{us}}(B^3))$ is a single point N_3 represented by $\{b_2 = d_2 = 0; a_2 = c_2 = e_2 = 1\}$, which is exactly $\pi_E(\mathcal{E}_\alpha^{\sigma_\beta})$. By Theorem 5.10 and its remark, the birational morphism $\varphi_E : \text{Mod}_\alpha^{\sigma_\beta}(B^3) \rightarrow \text{Mod}_{\alpha_\epsilon}^{\sigma_{\beta_\epsilon}^\vee}(B^2)$ is the blow-up at N_3 . Note that $\varphi_E(N_3) \in E_3(B^2)^\perp$, so it does not lie on the -1 -curve passing the two blow-up points. Hence $\text{Mod}_\alpha^{\sigma_\beta}(B^3)$ is the blow-up of $\mathbb{P}^2$ at three general points. Using Corollary 5.12, one can easily verify that the chambers of $\tau^{-1}\Sigma_\alpha(B^3)$ can be described as follows: the red-hexahedron core gives the blow-up at three general points, the six tetrahedrons all give the blow-up at two general points, and the rest gives either the blow-up at one point, $\mathbb{P}^1 \times \mathbb{P}^1$, or $\mathbb{P}^2$.

The above examples are well-known. The earliest reference that we found is [12].

Let us consider the anti-canonical weight for $\text{Rep}_\alpha(B^4)$, i.e., $\sigma_\beta = (2, 2, 2, 2, 2, -5)$, then σ_β is $\mathcal{E}_\alpha$ -effective. One can verify that $\epsilon = (0, 0, 0, 1, 1, 1)$ is an extremal ray of the cone $\Sigma_\alpha(B^4)$, so σ_β is a $E^\vee$ -regular weight and $\sigma_{\beta_\epsilon}^\vee = (2, 2, 2, -3, -3)$. For the same reason, $\text{Mod}_\alpha^{\sigma_\beta}(B^4)$ is smooth. Elements in $\text{Rep}_\alpha^{\sigma_{\beta_\epsilon}^\vee \cdot \text{us}}(Q)$ satisfy that $\text{rank}(a_4, b_4, c_4) = 1$, so $\pi_E(\text{Rep}_\alpha^{\sigma_{\beta_\epsilon}^\vee \cdot \text{us}}(Q))$ is a single point N_4 represented by $\{a_3 = b_3 = c_3 = d_3 = e_3 = f_3 = 1\}$, which is exactly $\pi_E(\mathcal{E}_\alpha^{\sigma_\beta})$. By Theorem 5.10 and its remark, the birational transformation $\varphi_E : \text{Mod}_\alpha^{\sigma_\beta}(B^4) \rightarrow \text{Mod}_{\alpha_\epsilon}^{\sigma_{\beta_\epsilon}^\vee}(B^3)$ is the blow-up at N_4 . Note that $\varphi_E(N_4) \in E_{uv}(B^3)^\perp, \forall u, v$, so it does not lie on any -1 -curve passing two blow-up points. Hence $\text{Mod}_\alpha^{\sigma_\beta}(B^4)$ is the blow-up of $\mathbb{P}^2$ at four general points. The chambers of $\tau^{-1}\Sigma_\alpha(B^4)$ has a similar structure.

If $\Sigma_\alpha^\heartsuit(Q)$ is empty, then according to Corollary 5.12, for almost every weight σ_β , we can find an exceptional E such that φ_E is an isomorphism. In this sense, we say that

Definition 5.17. (Q, α) is *weakly reduced* if $\Sigma_\alpha^\heartsuit(Q)$ is non-empty. (Q, α) is *reduced* if there is a weight σ_β such that φ_E is not an isomorphism for any exceptional representation E . (Q, α) is *strongly reduced* if there is a weight σ_β such that $\text{Mod}_\alpha^{\sigma_\beta}(Q)$ is not a moduli for any quiver having vertices less than that of Q . We also call the

above triple $(Q, \alpha, \sigma_\beta)$ reduced and strongly reduced. (Q, α) is *minimal* if its core is the same as its cone.

It is possible that (Q, α) is weakly reduced but not reduced, see Example 5.22. In this case, all possible GIT quotients inside the core already appear on the shell. However, we do not know if strongly reduced is really stronger than reduced.

Conjecture 5.18. “Strongly reduced” and “reduced” are equivalent.

Conjecture 5.19. If (Q, α) is reduced, then the weak core coincides with the core.

Starting with a triple $(Q, \alpha, \sigma_\beta)$ as in the beginning of this section, the first step to study the moduli space $\text{Mod}_\alpha^{\sigma_\beta}(Q)$ is to make the triple reduced. This can be done as follows. Find a real root ϵ orthogonal to α , if β falls into the two situation of Proposition 5.6, then we project it. Although the second criterion is sharp in certain cases (Example 5.16), it is just a sufficient condition in general. In practise, it may be not as useful as elementary arithmetic consideration. However, the main difficulty is that we do not know a good algorithm to detect real roots orthogonal to α .

Example 5.20. (Example 2.12 continued)

What happened if we take the anti-canonical weight again for $\text{Rep}_\alpha(B^{4,1})$? In this case, $\sigma_\beta = (2, 2, 2, 2, 0, -5)$, then it has strictly semi-stable points this time. One can verify that σ_β is weakly $(\mathcal{E}_1)_\alpha$ -effective but not $(\mathcal{E}_1)_\alpha$ -effective, so by Corollary 5.12, $\text{Mod}_\alpha^{\sigma_\beta}(B^{4,1})$ is still the blow-up of $\mathbb{P}^2$ at four general points. We leave it for interested readers to verify that the core is empty, i.e., (Q, α) is not reduced, so the only GIT quotients for $\text{Rep}_\alpha(B^{4,1})$ are the blow-up of n points of $\mathbb{P}^2$, where $n \leq 4$, and $\mathbb{P}^1 \times \mathbb{P}^1$.

Conjecture 5.21. Those are all the possible 2-dimensional GIT quotients in the quiver setting.

Example 5.22. (Example 3.7 continued) The cone $\Sigma_\alpha(Q)$ is generated by two extremal rays $(1, 1, 0)$ and $(3, 2, 2)$. With a little effort, one can show that the core $\Sigma_\alpha^\circ(Q)$ is cut out by a single real root $(1, 2, 0)$. So the core is generated by two extremal rays $(1, 1, 0)$ and $(4, 3, 2)$. But an elementary arithmetic argument can show that the quotient is constantly $\mathbb{P}^2$.

Example 5.23. It is possible that φ_E is not a morphism, i.e., strictly birational. Take any weight in the green area of $\Sigma_\alpha(B^2)$, then we see from the picture that φ_E induces a birational transformation $\mathbb{P}^2 \rightarrow \mathbb{P}^1 \times \mathbb{P}^1$, which is strict.

One can blame this example for the birational transformation crosses too many walls. In fact, we will see in the next section that crossing a part of shell which does not intersect any other wall behaves quite agreeable and can be described explicitly.

6. THE SHELL-CROSSING

A fundamental problem in the variational GIT is to describe how the quotients change when the weight crosses a single wall. As shown in the example 5.23, the birational transformation φ_E constructed in Theorem 5.10 can cross several walls. However, we can always appropriately choose weights such that a *piece* of the shell is the only wall being crossed.

Remarkably, Michael Thaddeus gave an beautiful solution to the above problem in [19]. Let us recall some of his general results. Let G be a reductive group over k acting on a quasi-projective variety over k . Suppose that L_+ and L_- are two ample G -linearization such that if $L(t) = L_+^t L_-^{1-t}$ for $t \in [-1, 1]$, there exists $t_0 \in (-1, 1)$ such that $X^{\text{ss}}(t) = X^{\text{ss}}(+)$ for $t > t_0$ and $X^{\text{ss}}(t) = X^{\text{ss}}(-)$ for $t < t_0$. This certainly happens when we cross a wall only at $L(t_0)$ through the line segment $L_+ L_-$ in the G -ample cone. We denote

$$\begin{aligned} X^\pm &:= X^{\text{ss}}(\pm) \setminus X^{\text{ss}}(\mp); \\ X^0 &:= X^{\text{ss}}(0) \setminus (X^{\text{ss}}(+)) \cup X^{\text{ss}}(-). \end{aligned}$$

It is easy to see that $X^\pm \subset X^0$ [19, Lemma 4.1].

Let $x \in X^0$ be a smooth point such that $G \cdot x$ is closed in $X^{\text{ss}}(0)$ and $G_x \cong k^*$. Since $x \in X^{\text{ss}}(0)$, G_x acts trivially on the fiber $(L_0)_x$. Assume that it acts non-trivially on $(L_+)_x$ with some negative weight v_+ , then it acts on $(L_-)_x$ with some positive weight v_- . We require that two weights are coprime: $(v_+, v_-) = 1$. It is shown that over a neighborhood of x in $X^0 //_0 G$, $X^\pm //_\pm G$ are locally trivial fibrations with fiber the weighted projective space $\mathbb{P}(|\omega_i^\pm|)$. If furthermore all $\omega_i^\pm = \pm\omega$ for some ω , then

Lemma 6.1. [19, Theorem 4.8] *Over a neighborhood of x in $X^0 //_0 G$, $X^\pm //_\pm G$ are naturally isomorphic to the projective bundles $\mathbb{P}W^\pm$, their normal bundles are naturally isomorphic to $\pi_\pm^* W^\mp(-1)$, and the blow-ups of $X //_\pm G$ at $X^\pm //_\pm G$, and of $X //_0 G$ at $X^0 //_0 G$, are all naturally isomorphic to the fibred product $X //_- G \times_{X //_0 G} X //_+ G$.*

What is $X^\pm$ and X^0 in our setting? Let us first make one simple observation on the walls of $\Sigma_\alpha(Q)$. We write H_ω for the hyperplane defined by $\langle \omega, \cdot \rangle_Q = 0$, then the set of all walls is contained in the union of H_ω for all indivisible roots $\omega < \alpha$. Let C^+, C^- be two adjacent chambers with W being a common wall whose supporting hyperplane is given by $\langle \omega, \cdot \rangle_Q = 0$ for some indivisible root ω . Here, we assume adjacency in a quite strong sense that W has codimension one. In this case, the strictly semi-stable representations on W must have a subrepresentation of dimension an integral point in the cone spanned by ω and $\alpha - \omega$. For simplicity, from now on let us assume that

$$(\odot) \quad \alpha, \alpha - \omega \text{ are indivisible, and } 2\omega \not< \alpha, 2(\alpha - \omega) \not< \alpha.$$

Note that with the assumption that α is indivisible, there is no strictly semi-stable points in C^+ and C^- , so in particular the corresponding quotients are smooth.

Let $\beta_\pm$ be an interior point of $C^\pm$, and β_0 be the intersection of $\beta_+ \beta_-$ with W . By definition, there is a strictly σ_{β_0} -semi-stable representation M with a subrepresentation L of dimension γ such that $\langle \gamma, \beta_0 \rangle_Q = 0$ but $\langle \gamma, \beta_+ \rangle_Q \langle \gamma, \beta_- \rangle_Q < 0$. By assumption $\odot$, we can assume $\gamma = \omega$ without loss of generality. By our convention that $\langle \omega, \beta_+ \rangle_Q > 0$, M is σ_{β_+} -stable but σ_{β_-} -unstable. We conclude that

$$\begin{aligned} X^+ &= \text{Rep}_{\alpha}^{\sigma_{\beta_+} \cdot \text{ss}}(Q) \cap \text{Rep}_{\omega \hookrightarrow \alpha}(Q) := \text{Rep}_{\omega \hookrightarrow \alpha}^{\sigma_{\beta_+} \cdot \text{ss}}(Q), \\ X^- &= \text{Rep}_{\alpha}^{\sigma_{\beta_-} \cdot \text{ss}}(Q) \cap \text{Rep}_{\alpha \twoheadrightarrow \omega}(Q) := \text{Rep}_{\alpha \twoheadrightarrow \omega}^{\sigma_{\beta_-} \cdot \text{ss}}(Q). \end{aligned}$$

With a little effort, one can show that $X^0 = \text{Rep}_{\alpha}^{\sigma_{\beta_0} \cdot \text{ss}}(Q) \cap \text{Rep}_{\omega \oplus \alpha - \omega}(Q)$, but we do not need this in the future. Readers shouldn't find any difficulty to formulate these sets without assumption $\odot$. Our main interest is the case when $\omega = \epsilon$ is a real Schur root and $\epsilon \perp \alpha$. Then $W = S$ is called a *piece* of the shell, and by

our convention C^+ is inside the core. In view of the next lemma, it is usually an uninteresting case when ϵ is not exceptional to α . So we assume that ϵ is exceptional to α .

Lemma 6.2. *Assume that $\alpha - \epsilon$ and α are indivisible.*

- (i) *If ϵ is orthogonal but not exceptional to α , then both $\text{Rep}_{\epsilon \hookrightarrow \alpha}^{\sigma_{\beta+} \cdot \text{ss}}(Q)$ and $\text{Rep}_{\alpha \twoheadrightarrow \epsilon}^{\sigma_{\beta-} \cdot \text{ss}}(Q)$ are empty.*
- (ii) *If ϵ is exceptional to α , then*

$$\begin{aligned} \text{Rep}_{\epsilon \hookrightarrow \alpha}^{\sigma_{\beta+} \cdot \text{ss}}(Q) &= \text{Rep}_{\alpha}^{\sigma_{\beta+} \cdot \text{ss}}(Q) \cap \mathcal{E}_{\alpha} = \mathcal{E}_{\alpha}^{\sigma_{\beta}}, \\ \text{Rep}_{\alpha \twoheadrightarrow \epsilon}^{\sigma_{\beta-} \cdot \text{ss}}(Q) &= \text{Rep}_{\alpha}^{\sigma_{\beta-} \cdot \text{ss}}(Q) \cap \text{GL}_{\alpha} \cdot \tilde{\pi}_E(\mathcal{E}_{\alpha}) = \text{GL}_{\alpha} \cdot \tilde{\pi}_E(\mathcal{E}_{\alpha}^{\sigma_{\beta}}). \end{aligned}$$

Proof. (i) Suppose that ϵ is not exceptional to α and there is a $\sigma_{\beta+}$ -semi-stable representation in the irreducible set $\text{Rep}_{\epsilon \hookrightarrow \alpha}(Q)$, then general representation there is $\sigma_{\beta+}$ -semi-stable. We can assume that such a general representation M has E as its subrepresentation and $N = M/E$ is general in $\text{Rep}_{\alpha-\epsilon}(Q)$. Then by Corollary 3.6, $\text{hom}_Q(E, N) > 0$. But for any morphism in $\text{hom}_Q(E, N)$, the only possible dimension for the image is either ϵ , or a fraction of $\alpha - \epsilon$ or α , because both E and N are semi-stable on W . The latter is ruled out by assumption. For the first case, we note that $\text{hom}_Q(E, N/E) > 0$ because $\mathcal{E}_{\alpha}$ is empty. So we can apply the similar argument inductively to N/E . The other half can be proved similarly.

- (ii) The proof is similar to (i). □

Let us examine the assumption of the lemma in this setting. Fortunately, smoothness is not an issue for us. $G \cdot x$ is closed simply means that the representation is *polystable*, i.e., a direct sum of stable representations. The condition $G_x \cong k^*$ is necessary as shown in [19, Counterexample 5.8]. In our setting, this condition is equivalent to that the polystable representation M is a direct sum of two non-isomorphic stable representations. Then its stabilizer is a 2-dimensional torus modulo the multi-diagonally embedded k^* . With assumption $\odot$, the only possible dimensions of stable summands are ϵ and $\alpha - \epsilon$, but $2\epsilon \neq \alpha$, so we don't need to worry about this. Next, the coprime condition $(v_+, v_-) = 1$ is not a problem as long as the crossing is general. Finally, the condition for weights ϵ_i is always satisfied by [19, Proposition 4.9].

Theorem 6.3. *Suppose that assumption $\odot$ holds, and S is a piece of shell with supporting hyperplane $\langle \epsilon, \cdot \rangle_Q$. If β is $E^{\vee}$ -regular and S is the only wall intersecting $\beta \tilde{\beta}_{\epsilon}^{\vee}$, then $\varphi_E : \text{Mod}_{\alpha}^{\sigma_{\beta}}(Q) \rightarrow \text{Mod}_{\alpha_{\epsilon}}^{\sigma_{\beta_{\epsilon}}^{\vee}}(Q_E)$ is the blow-up of $\text{Mod}_{\alpha_{\epsilon}}^{\sigma_{\beta_{\epsilon}}^{\vee}}(Q_E)$ along the irreducible subvariety $\tilde{q}_E \pi_E(\text{Rep}_{\alpha \twoheadrightarrow \epsilon}^{\sigma_{\beta_{\epsilon}}^{\vee} \cdot \text{ss}}(Q))$. If the blow-up loci is non-empty, then it has dimension $-\langle \alpha - \epsilon, \epsilon \rangle_Q$ and its exceptional loci is $q(\text{Rep}_{\epsilon \hookrightarrow \alpha}^{\sigma_{\beta} \cdot \text{ss}}(Q))$.*

Proof. With the assumption $\odot$, the condition of Lemma 6.1 holds for every $x \in X^0$, so its conclusion holds globally. Since the positive quotient is smooth and hence locally factorial, the codimension-one subvariety $\text{Rep}_{\epsilon \hookrightarrow \alpha}^{\sigma_{\beta} \cdot \text{st}}(Q)$ descends to a Cartier divisor in the positive quotient. So nothing happens after blowing it up. In the meanwhile, by Corollary 5.12 the negative quotient is isomorphic to $\text{Mod}_{\alpha_{\epsilon}}^{\sigma_{\beta_{\epsilon}}^{\vee}}(Q_E)$ and under this identification $q(\text{Rep}_{\alpha \twoheadrightarrow \epsilon}^{\sigma_{\beta_{\epsilon}}^{\vee} \cdot \text{ss}}(Q))$ becomes $\tilde{q}_E \pi_E(\text{Rep}_{\alpha \twoheadrightarrow \epsilon}^{\sigma_{\beta_{\epsilon}}^{\vee} \cdot \text{ss}}(Q))$. So our claim follows from Lemma 6.1. For the statement on the dimension of the blow-up loci, it suffice to verify the assumption in Proposition 3.8 holds. But if the

assumption is not satisfied, it is clear from assumption $\ominus$ that the blow-up loci has to be empty. $\square$

Without assumption $\ominus$, we can still say a lot about the birational morphism. For example, φ_E is a Lune type stratification, whose local structure can be determined by the local quiver setting [1], but we do not want to pursue this. At least, for all known *interesting* examples [8], assumption $\ominus$ is always satisfied. To get interesting examples, we certainly hope that the blow-up is non-trivial. Roughly speaking, the number $-\langle \alpha - \epsilon, \epsilon \rangle_Q$ should lie in a proper range. When it is too small, for example zero, S must be on the boundary of $\Sigma_\alpha(Q)$ if S exists. When it is one, we again get a blow-up along a Cartier divisor. But when the number is too large, it is very likely that the set $\text{Rep}_{\alpha \rightarrow \epsilon}(Q)$ is trapped into the null-cone. So in general for a n -dimensional quotient, we hope that $-\langle \alpha - \epsilon, \epsilon \rangle_Q$ is within the range $[2, n]$. However, this is by no means a sufficient condition. For example, one can verify that $-\langle \alpha - \epsilon_2, \epsilon_2 \rangle_Q = 2$ in Example 2.12, but the blow-up loci is empty. If the blow-up is non-trivial, then we say that piece of shell is *hard* in sense that one needs blow-up to cross it.

As pointed out in [19], there are basically two typical styles for single wall-crossings. One is that $X//_-G \rightarrow X//_0G$ is isomorphism while $X//_+G \rightarrow X//_0G$ is divisorial; the other is that both $X//_-G \rightarrow X//_0G$ and $X//_+G \rightarrow X//_0G$ are *small*, and usually this results a *flip* $X//_-G \dashrightarrow X//_+G$. According to Theorem 6.3, a single shell-crossing almost always falls into the first category. Of course, there are other types of wall-crossings in the quiver setting. For some mysterious reason, they seem to exclusively fall into the second category. We do not want to pursue this in this notes, because they seem unrelated to our theme tilting. For this type of examples, we refer the readers to [8].

Example 6.4. (Example 2.13 continued) We take the weight σ_β inside the core, which is generated by $(2, 3, 4), (1, 3, 3)$. It is easy to verify all the conditions of Theorem 6.3 are satisfied. The moduli downstairs $\text{Mod}_{\alpha_\epsilon}^{\sigma_\beta^\vee}(Q_E)$ is clearly the projective space $\mathbb{P}^3$. The blow-up loci (2.1) is thus a twisted cubic. Therefore, the moduli is the blow-up of $\mathbb{P}^3$ along a twisted cubic.

Problem 6.5. If $\text{Mod}_{\alpha^\beta}(Q)$ is the blow-up of some smooth variety X along an irreducible subvariety Y , can we always find a real root ϵ such that $X = \text{Mod}_{\alpha_\epsilon}^{\sigma_\beta^\vee}(Q_E)$ and $Y = \tilde{q}_E \pi_E(\text{Rep}_{\alpha \rightarrow \epsilon}^{\sigma_\beta^\vee, \text{ss}}(Q))$ as in Theorem 6.3?

7. INDUCED AMPLE DIVISORS

Let $q : \text{Rep}_{\alpha}^{\sigma_\beta, \text{ss}}(Q) \rightarrow \text{Mod}_{\alpha^\beta}(Q)$ still be the quotient map. This is an equivariant proper map, that is, it maps GL_α -invariant closed sets to closed sets. For any GL_α -invariant divisor C in $\text{Rep}_{\alpha}^{\sigma_\beta, \text{ss}}(Q)$, if its support contains a σ_β -stable point, then it descends to a (Weil) divisor $q_*(C)$ in $\text{Mod}_{\alpha^\beta}(Q)$. Since we assumed that the characteristic of k is 0, this push-forward is nothing but take the invariants of the subscheme C then throw away the components of codimension greater than one. So for any $N \in \text{Rep}_\gamma(Q)$, if the divisor C_N contains a σ_β -stable point, then it descends to an effective divisor $D_N^{\sigma_\beta} := q_*(C_N \cap \text{Rep}_{\alpha}^{\sigma_\beta, \text{ss}}(Q))$ in $\text{Mod}_{\alpha^\beta}(Q)$. For what follows, whenever we write $D_N^{\sigma_\beta}$, we always assume it is a divisor. The next lemma can be deduced from the sequence (1.1).

Lemma 7.1. [6, Lemma 1] *If $0 \rightarrow N_1 \rightarrow N \rightarrow N_2 \rightarrow 0$ is an exact sequence with $\langle \alpha, \dim_Q(N_1) \rangle = 0$, then $c_N = c_{N_1} c_{N_2}$ and thus $D_N^{\sigma_\beta} = D_{N_1}^{\sigma_\beta} + D_{N_2}^{\sigma_\beta}$.*

Lemma 7.2. *Any divisor of form $D_N^{\sigma_\beta}$ are equivalent, where N has a fixed dimension γ .*

Proof. Consider two such divisors $D_{N_1}^{\sigma_\beta}, D_{N_2}^{\sigma_\beta}$. Since the divisor is nontrivial, α is σ_γ -semi-stable, then α is $\sigma_{(n\beta-\gamma)}$ -semi-stable for $n \gg 0$. So we can choose some $N_0 \in \text{Rep}_{(n\beta-\gamma)}(Q)$ such that $D_{N_0}^{\sigma_\beta}$ is non-trivial. Now consider the representation $N = N_1 \oplus N_2 \oplus N_0$. By Lemma 7.1, $D_N^{\sigma_\beta} = D_{N_1}^{\sigma_\beta} + D_{N_2 \oplus N_0}^{\sigma_\beta} = D_{N_2}^{\sigma_\beta} + D_{N_1 \oplus N_0}^{\sigma_\beta}$. Since both $N_1 \oplus N_0$ and $N_2 \oplus N_0$ has dimension $n\beta$, the divisor $D_{N_1 \oplus N_0}^{\sigma_\beta} - D_{N_2 \oplus N_0}^{\sigma_\beta}$ corresponds to a rational function on $\text{Mod}_\alpha^{\sigma_\beta}(Q)$. Hence, $D_{N_1}^{\sigma_\beta}$ and $D_{N_2}^{\sigma_\beta}$ are equivalent. $\square$

We denote the class of $D_N^{\sigma_\beta}$ by $D_\gamma^{\sigma_\beta}$. We call it the *induced divisor from weight σ_γ* . When $\gamma = \beta$, we simply write D_β for the ample divisor $D_\beta^{\sigma_\beta}$. We keep our assumption that β is $E^\vee$ -regular. Then Corollary 5.12 tells us that two moduli spaces $\text{Mod}_\alpha^{\sigma_\beta}(Q_E)$ and $\text{Mod}_\alpha^{\sigma_{\beta^\epsilon}}(Q)$ are isomorphic, and it is clear from Lemma 4.2 that

Lemma 7.3. *The ample divisors D_β and D_{β^ϵ} are equivalent.*

Remember that $(\beta^\vee)^\epsilon = \tilde{\beta}_\epsilon^\vee$. Under the above identification, the ample divisor $D_{\beta^\vee}$ can be represented by $D_N^{\sigma_{\tilde{\beta}_\epsilon^\vee}}$ for some general $N \in \text{Rep}_{\tilde{\beta}_\epsilon^\vee}(E^\perp)$. Since the GIT quotients are normal, the fundamental points of φ_E in Theorem 5.10 has codimension at least 2 [10, Lemma V.5.1]. So it makes sense to talk about pulling back a divisor.

Lemma 7.4. $\varphi_E^*(D_{\beta^\vee}) = D_{\tilde{\beta}_\epsilon^\vee}^{\sigma_\beta}$ wherever φ_E is an isomorphism.

Proof. It is enough to show that $\varphi_E^*(D_N^{\sigma_{\tilde{\beta}_\epsilon^\vee}}) = D_N^{\sigma_\beta}$ for some $N \in \text{Rep}_{\tilde{\beta}_\epsilon^\vee}(E^\perp)$. Since the push-forward q_* is essentially taking invariants, it suffices to consider the reduced part of C_N . Due to Lemma 4.2, $\tilde{\pi}_E(C_N)_{\text{red}} \subseteq \hat{q}(C_N)_{\text{red}}$, where $\hat{q}$ is the quotient map $\text{Rep}_\alpha(Q) \rightarrow \text{Mod}_\alpha(Q)$. The other half $\tilde{\pi}_E(C_N)_{\text{red}} \supseteq \hat{q}(C_N)_{\text{red}}$ is clear from the adjointness, hence $\tilde{\pi}_E(C_N)_{\text{red}} = \hat{q}(C_N)_{\text{red}}$. By the construction of φ_E and the definition of $D_N^{\sigma_{\tilde{\beta}_\epsilon^\vee}}$ and $D_N^{\sigma_\beta}$, we know that the equation holds wherever φ_E is an isomorphism. $\square$

Now we suppose that σ_β is $\mathcal{E}_\alpha$ -effective and $\mathcal{E}_\alpha$ contains a σ_β -stable point. Note that the support of $C_{\tau E}$ are precisely $\text{Rep}_\alpha(Q) \setminus E^\perp$. By Corollary 3.6, $\mathcal{E}_\alpha$ has a scheme structure inherited from $C_{\tau E}$ as its open subscheme, and $E_\beta := q_*(\overline{\mathcal{E}_\alpha^{\sigma_\beta}})$ is an irreducible divisor. It follows immediately from the definition of $D_{\tau E}^{\sigma_\beta}$ that if $D_{\tau E}^{\sigma_\beta}$ is irreducible, then $D_{\tau E}^{\sigma_\beta} = E_\beta$.

Lemma 7.5. *In the situation of Theorem 6.3, $D_{\tau E}^{\sigma_\beta}$ is irreducible.*

Proof. We show that if $C_{\tau E}$ has an irreducible components other than C_ϵ , then those components contain entirely σ_β -unstable points. Suppose that there is a σ_β -semi-stable representation M in other components, then the general rank from E to M is not ϵ , say γ , so $\langle \gamma, \beta \rangle \geq 0$. But $\epsilon \perp \beta$, so $\langle \gamma, \beta \rangle \leq 0$, and thus $\langle \gamma, \beta \rangle = 0$, but this is ruled out by assumption $\odot$. $\square$

Theorem 7.6. *Suppose that $D_{\tau E}^{\sigma_\beta}$ is irreducible and $\text{hom}_Q(\alpha - \epsilon, \tilde{\beta}_\epsilon^\vee) = 0$, then $D_\beta = \varphi_E^*(D_{\beta_\epsilon^\vee}) - \langle \epsilon, \beta \rangle_Q E_\beta$.*

Proof. Let $D_{N'}^{\sigma_\beta}$ be a representative for D_β , and consider $N = N' \oplus \langle \epsilon, \beta \rangle_Q \tau E$. The definition of N make sense because $\langle \epsilon, \beta \rangle_Q > 0$. Then by Lemma 7.1

$$(7.1) \quad D_N^{\sigma_\beta} = D_{N'}^{\sigma_\beta} + \langle \epsilon, \beta \rangle_Q D_{\tau E}^{\sigma_\beta} = D_\beta + \langle \epsilon, \beta \rangle_Q E_\beta.$$

Next, we claim that for general $N \in \text{Rep}_{\tilde{\beta}_\epsilon^\vee}(Q)$, the support of $D_N^{\sigma_\beta}$ cannot contains that of E_β so that their intersection has codimension at most two. This is equivalent to that C_N cannot contain $\text{Rep}_{\epsilon \hookrightarrow \alpha}(Q)$. A general element V in the latter is an extension $0 \rightarrow E \rightarrow V \rightarrow W \rightarrow 0$ with W general in $\text{Rep}_{\alpha-\epsilon}(Q)$. Since $\text{hom}_Q(\epsilon, \tilde{\beta}_\epsilon^\vee) = 0$ and $\text{hom}_Q(\alpha - \epsilon, \tilde{\beta}_\epsilon^\vee) = 0$, we have that $\text{hom}_Q(V, N) = 0$ so $V \notin C_N$.

Since φ_E is an isomorphism outside E_β and the support of $D_N^{\sigma_\beta}$ intersects E_β in codimension at most two, we can apply Lemma 7.2 and 7.4 and conclude that $\varphi_E^*(D_{\beta_\epsilon^\vee}) = D_N^{\sigma_\beta}$. Then our result $D_\beta = \varphi_E^*(D_{\beta_\epsilon^\vee}) - \langle \epsilon, \beta \rangle_Q E_\beta$ follows from the equation (7.1). $\square$

Example 7.7. Let us consider quiver B^1 with $\alpha = (1, 1, 1)$ and $\sigma_\beta = (1, 1, -2)$, then $\tilde{\beta}_\epsilon^\vee = (4, 4, 2)$ and $\sigma_{\beta_\epsilon^\vee} = (2, -2)$. We knew that $\varphi_E : \text{Mod}_\alpha^{\sigma_\beta}(B^1) \rightarrow \text{Mod}_{\alpha_\epsilon}^{\sigma_{\beta_\epsilon^\vee}}(\Theta_3)$ is the blow-up of $\mathbb{P}^2$ at one point, and $D_{\beta_\epsilon^\vee}$ clearly corresponds to $\mathcal{O}(2)$ on $\mathbb{P}^2$. By Theorem 7.6, $D_\beta = \varphi_E^*(D_{\beta_\epsilon^\vee}) - \langle \epsilon, \beta \rangle_Q E_\beta = \varphi_E^*(\mathcal{O}(2)) - E_\beta$. So its linear series corresponds to $|\mathcal{O}(2)|$ with one assigned base point on $\mathbb{P}^2$. In particular, $\alpha \circ \beta := h^0(\text{Mod}_\alpha^{\sigma_\beta}(B^1), D_\beta) = 6 - 1 = 5$.

Example 7.8. Let us consider quiver C_3^6 with $\alpha = (1, 4, 3)$ and $\sigma_\beta = (3, 3, -5)$, then $\tilde{\beta}_\epsilon^\vee = (12, 16, 12)$ and $\sigma_{\beta_\epsilon^\vee} = (3, -3)$. We knew that $\varphi_E : \text{Mod}_\alpha^{\sigma_\beta}(C_3^6) \rightarrow \text{Mod}_{\alpha_\epsilon}^{\sigma_{\beta_\epsilon^\vee}}(C_2^1)$ is the blow-up of $\mathbb{P}^3$ along a twisted cubic, and $D_{\beta_\epsilon^\vee}$ clearly corresponds to $\mathcal{O}(3)$ on $\mathbb{P}^3$. By Theorem 7.6, $D_\beta = \varphi_E^*(D_{\beta_\epsilon^\vee}) - \langle \epsilon, \beta \rangle_Q E_\beta = \varphi_E^*(\mathcal{O}(3)) - E_\beta$. So its linear series corresponds to $|\mathcal{O}(3)|$ with assigned base points a twisted cubic. The cubic can be defined by the ideal $(x^2 - wy, y^2 - xz, zw - xy)$, then one can verify that $\alpha \circ \beta := h^0(\text{Mod}_\alpha^{\sigma_\beta}(C_3^6), D_\beta) = 10$.

Among all the weights, the most interesting one is the one related to the anti-canonical character of a representation [11].

Definition 7.9. The *anti-canonical character* σ_{ac} of the representation V is the character of the representation $\det V$.

Let us compute the anti-canonical character in the quiver setting, that is, $G = \text{GL}_\alpha$ acts on $V = \text{Rep}_\alpha(Q)$ by the base change.

$$\begin{aligned} \sigma_{ac} &= \sum_{a \in Q_1} \alpha(ta) \det_{ha} - \alpha(ha) \det_{ta} \\ &= \sum_{q \in Q_0} \left(\sum_{a \in h^{-1}q} \alpha(ta) - \sum_{a \in t^{-1}q} \alpha(ha) \right) \det_q. \end{aligned}$$

So it coincides with the weight $\langle \alpha, \cdot \rangle_Q - \langle \cdot, \alpha \rangle_Q = \langle \alpha + \tau^{-1}\alpha, \cdot \rangle_Q = -\langle \cdot, \alpha + \tau\alpha \rangle_Q$. We will show under some technical condition $\circledast$, which we think maybe unnecessary in general, that the induced divisor from the anti-canonical weight coincide with

the anti-canonical class. Let $S = \text{Rep}_\alpha^{\sigma_\beta \cdot \text{ss}}(Q) \setminus \text{Rep}_\alpha^{\sigma_\beta \cdot \text{st}}(Q)$ be the strict semi-stable points, the condition $\circledast$ requires $\text{codim}(q(S), \text{Mod}_\alpha^{\sigma_\beta}(Q)) \geq 2$.

For any GL_α -module W , we denote by $\mathcal{W}$ the sheaf over $\text{Mod}_\alpha^{\sigma_\beta}(Q)$ associated to the module of covariants $(k[\text{Rep}_\alpha(Q)] \otimes W^*)^{\text{GL}_\alpha^{\sigma_\beta}}$. It is a vector bundle over the geometric quotient $\mathcal{M}^{\text{st}} := q(\text{Rep}_\alpha^{\sigma_\beta \cdot \text{st}}(Q))$.

Proposition 7.10. *Under assumption $\circledast$, the induced divisor $D_{ac}^{\sigma_\beta}$ from the anti-canonical weight is the anti-canonical class on $\text{Mod}_\alpha^{\sigma_\beta}(Q)$. In particular, $\text{Mod}_\alpha^{\sigma_{ac}}(Q)$ is a Fano variety.*

Proof. Let $\hat{G} = \text{GL}_\alpha^{\sigma_\beta} / k^*$, where k^* is embedded multi-diagonally. Note that $\hat{G}$ acts faithfully on $\text{Rep}_\alpha^{\sigma_\beta \cdot \text{st}}(Q)$ and $\mathcal{M}^{\text{st}}$ is smooth. There is a generalized Euler sequence on $\mathcal{M}^{\text{st}}$:

$$0 \rightarrow \mathcal{O}_{\mathcal{M}^{\text{st}}}^{\dim \hat{G}} \rightarrow \mathcal{R}ep_\alpha(Q) \rightarrow \mathcal{T} \rightarrow 0,$$

where $\mathcal{R}ep_\alpha(Q)$ is the vector bundle corresponding to the GL_α -module $\text{Rep}_\alpha(Q)$ and $\mathcal{T}$ is the tangent bundle on $\mathcal{M}^{\text{st}}$. Taking the exterior power to the sequence, we see that the statement holds on $\mathcal{M}^{\text{st}}$. But the assumption $\circledast$ says the complement of $\mathcal{M}^{\text{st}}$ has codimension greater than one, so the two classes agree. $\square$

In view of Lemma 5.15, it is interesting to compute $\langle \epsilon, ac \rangle_Q$. This is equal to $\langle \epsilon, \alpha + \tau\alpha \rangle_Q = -\langle \alpha, \epsilon \rangle_Q = -\langle \alpha - \epsilon, \epsilon \rangle_Q - 1$, which is one less than the codimension of the blow-up loci in Theorem 6.3. Of course, this agrees with the general blow-up formula for the canonical divisor [10, Exercise II.8.5].

Example 7.11. (Example 5.16 continued) We now can finish the discussion of this example. Remember that all the weights that we took are anti-canonical, so $h^0(\text{Mod}_\alpha^{\sigma_\beta}(B^n), D_{ac}) = 10 - n$. More generally, the Hilbert polynomial of D_{ac} on $\text{Mod}_\alpha^{\sigma_\beta}(B^n)$ is $\frac{1}{2}[(9 - n)x^2 + (9 - n)x + 2]$.

ACKNOWLEDGEMENT

The author would like to thank Professor Harm Derksen for carefully reading the manuscript, for his great patience, and especially his support for very long time. The author also wants to thank Professor Rob Lazarsfeld, from whom he learned the geometric invariant theory. The author is grateful to Alastair King and Aidan Schofield's seminal papers [13, 16, 17], from which everything is originated; and Michael Thaddeus's excellent paper [19], which solved the most difficult part of this notes.
